Table of Contents (1)

Part I: Introduction

- Chap. 1: Motivation
- Chap. 2: Data Flow Analysis in a Nutshell
  - 2.1 Program Analyis
  - 2.2 Forward Analyses
  - 2.3 Backward Analyses
- Chap. 3: Taxonomy of DFA-Analyses

Table of Contents (2)

Part II: Intraprocedural Data Flow Analysis

- Chap. 4: Flow Graphs
- Chap. 5: The Intraprocedural DFA Framework
  - 5.1 The *MOP* Approach
  - 5.2 The *MaxFP* Approach
  - 5.3 Coincidence and Safety Theorem
  - 5.4 Examples: Available Expressions, Simple Constants
    - 5.4.1 Available Expressions
    - 5.4.2 Simple Constants
- Chap. 6: Partial Redundancy Elimination
  - 6.1 Motivation
  - 6.2 The PRE Algorithm of Morel&Renvoise
- Chap. 7: Busy Code Motion
  - 7.1 Preliminaries
  - 7.2 The *BCM*-Transformation

Table of Contents (3)

- Chap. 8: Lazy Code Motion
  - 8.1 Preliminaries
  - 8.2 The *ALCM*-Transformation
  - 8.3 The *LCM*-Transformation
  - 8.4 An Extended Example
- Chap. 9: Implementing Busy and Lazy Code Motion
  - 9.1 Implementing *BCM* and *LCM* on SI-Graphs
    - 9.1.1 Preliminaries
    - 9.1.2 Implementing BCM_ι
    - 9.1.3 Implementing LCM_ι
  - 9.2 Implementing *BCM* and *LCM* on BB-Graphs
    - 9.2.1 Preliminaries
    - 9.2.2 Implementing BCM_β
    - 9.2.3 Implementing LCM_β
  - 9.3 An Extended Example

Table of Contents (4)

- Chap. 10: Sparse Code Motion
- Chap. 11: Lazy Strength Reduction
- Chap. 12: More on Code Motion

12.1 Motivation
12.2 Code Motion vs. Code Placement
12.3 Interactions of Elementary Transformations
12.4 Paradigm Impacts
12.5 Further Code Motion Transformations

Table of Contents (5)

Part III: Interprocedural Data Flow Analysis

- Chap. 13: The Context Information Approach
- Chap. 14: The Functional Approach

14.1 The Base Setting

14.1.1 Local Abstract Semantics
14.1.2 The *IMOP* Approach
14.1.3 The *IMaxFP* Approach
14.1.4 Main Results
14.1.5 Algorithms
14.1.6 Applications

Table of Contents (6)

- Chap. 14 (Cont'd)
  - 14.2 The General Setting
    - 14.2.1 Local Abstract Semantics
    - 14.2.2 The $IMOP_{Stk}$ Approach
    - 14.2.3 The $IMaxFP_{Stk}$ Approach
    - 14.2.4 Main Results
    - 14.2.5 Algorithms
  - 14.3 Further Extensions
  - 14.4 Applications
  - 14.5 Interprocedural DFA: Framework and Toolkit

Part IV: Extensions, Other Settings

- Chap. 15: Alias Analysis
  - 15.1 Sources of Aliasing
  - 15.2 Relevance of Aliasing for Program Optimization
  - 15.3 Shape Analysis

Table of Contents (7)

- Chap. 16: Optimizations for Object-Oriented Languages
  - 16.1 Object Layout and Method Invocation
    - 16.1.1 Single Inheritance
    - 16.1.2 Multiple Inheritance
  - 16.2 Devirtualization of Method Invocations
    - 16.2.1 Class Hierarchy Analysis
    - 16.2.2 Rapid Type Analysis
    - 16.2.3 Inlining
  - 16.3 Escape Analysis
    - 16.3.1 Connection Graphs
    - 16.3.2 Intraprocedural Setting
    - 16.3.3 Interprocedural Setting
- Chap. 17: Program Slicing

Table of Contents (8)

Part V: Conclusions and Prospectives

- Chap. 18: Summary and Outlook
- Bibliography
- Appendix
  - A Mathematical Foundations
    - A.1 Sets and Relations
    - A.2 Partially Ordered Sets
    - A.3 Lattices
    - A.4 Complete Partially Ordered Sets
    - A.5 Fixed Point Theorems
  - B Intricacies of Basic Block Graphs
    - B.1 Motivation
    - B.2 Availability of Expressions
    - B.3 Constant Propagation and Folding
    - B.4 Faint Variables
    - B.5 Conclusion

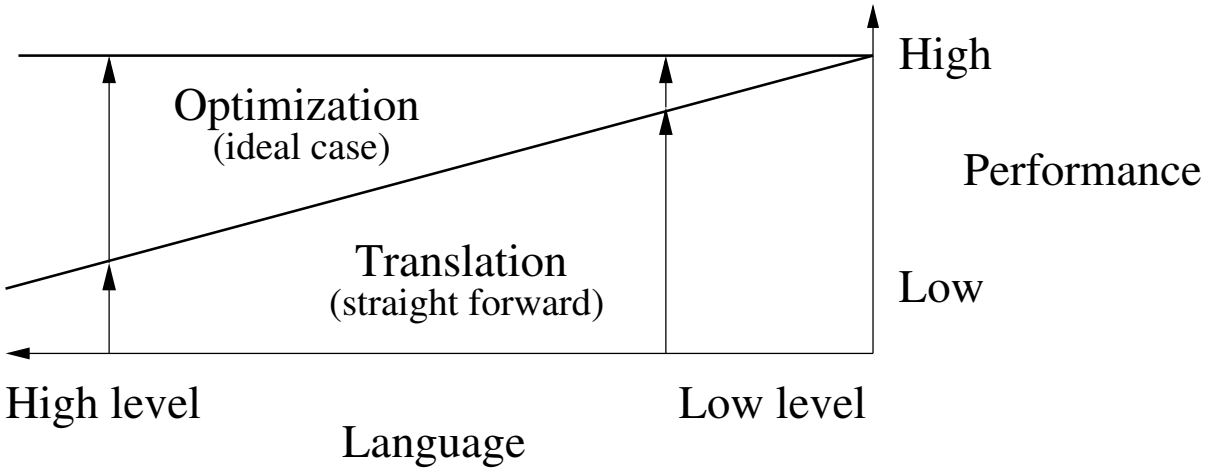
Languages and Their Perceived Performance



- Common perception is that high level languages/abstrac- tion gives low level of performance.
- Translation (straight forward) preserves semantics but does not exploit specific opportunities of lower level language with respect to performance.
- Optimization improves performance (misnomer: usually we do not achieve an "optimal" solution - but it is the ideal case)

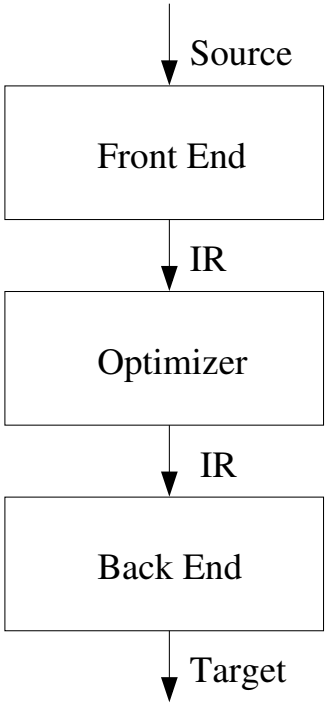
Generic Structure of an Optimizing Compiler



Goal of code optimization

- Discover, at compile-time, information about the run-time behavior of the program and use that information to improve the code generated by the compiler.

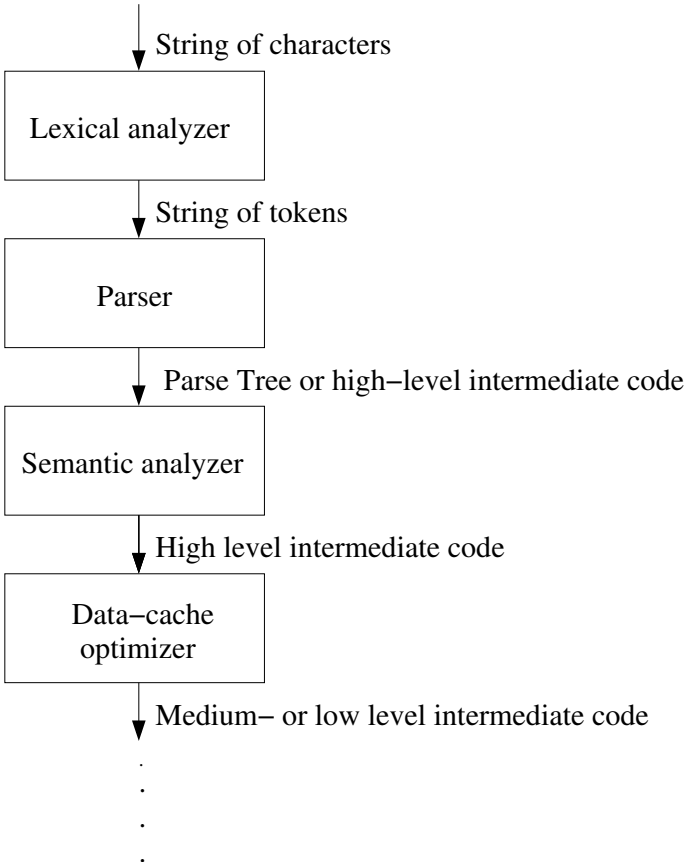
Model of a High Level Cache Optimizer



Adding data-cache optimization to an optimizing compiler

- Data-cache optimizations are most effective when applied to a high-level intermediate form.

Examples

- High-Level optimizations
  - IBM's PowerPC compiler: first translates to LL code (XIL) and then generates a HL representation (YIL) from it to do data-cache optimization.
  - Source-To-Source Optimizer Tools: Sage++, LLNL-ROSE, JTransformer.
- Mixed model
  - Sun Microsystem's compilers for SPARC
  - Intel's compilers for the 386 architecture family
  - Silicon Graphic's compilers for MIPS
- Low level model
  - IBM's compilers for PowerPC
  - Hewlett-Packard's compilers for PA-RISC.

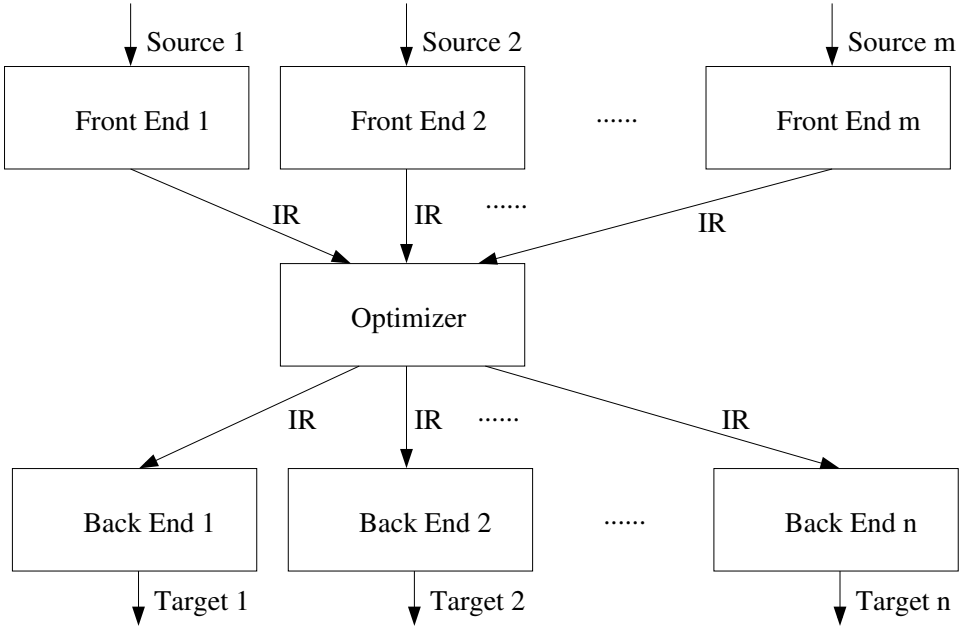
Practice: m-2-n Compilers and Optimizers



Idea: Decoupling of Compiler Front Ends from Back Ends

- Without IR: m source languages, n targets $\rightarrow m \times n$ compilers
- With IR: m Front Ends, n Back Ends
- Problem: Appropriate choice of the level of IR (possible solution: multiple levels of IR)

IR-Decoupling of Compiler Front/Back Ends

...is an application of the well-known UNCOL concept:

```
---------     ---------         --------
|  PL 1 |     |  PL 2 |   ...   |  PL n |
---------      --------         --------
    |             |                |
    ---------------------------------
                  |
                 \/
               ----------          Universal
               |  UNCOL  |      Computer Oriented
               ----------          Language
                  |
    ---------------------------------
    |             |                |
   \/            \/               \/
 ---------     ---------        ---------
 |  ML 1  |    |  ML 2 |   ...  |  ML m |
 ---------      --------        ---------
```

Intermediate Representation (IR)

- High level
  - quite close to source language
  - e.g. abstract syntax tree
  - code generation issues are quite clumsy at high-level
  - adequate for high-level optimizations (cache, loops)
- Medium level
  - represent source variables, temporaries, (and registers)
  - reduce control flow to conditional and unconditional branches
  - adequate to perform machine independent optimizations
- Low level
  - correspond to target-machine instructions
  - adequate to perform machine dependent optimizations

Different Kinds of Optimizations

...for different purposes, e.g.:

- Speeding up execution of compiled code
- Size of compiled code
  - when committed to read-only memory where size is an economic constraint
  - or code is transmitted over a limited-bandwidth communications channel
- Energy consumption
- Response to real-time events
- etc.

Considerations for Optimization

- Safety
  - correctness: generated code must have the same meaning as the input code
  - meaning: is the observable behavior of the program
- Profitability
  - improvement of code
  - trade offs between different kinds of optimizations
- Problems
  - reading past array bounds, pointer arithmetics, etc.

Scope of Optimization (1)

- Local
  - basic blocks
  - statements are executed sequentially
  - if any statement is executed the entire block is executed
  - limited to improvements that involve operations that all occur in the same block
- Intra-procedural (global)
  - entire procedure
  - procedure provides a natural boundary for both analysis and transformation
  - procedures are abstractions encapsulating and insulating run-time environments
  - opportunities for improvements that local optimizations do not have

Chap. 17
Chap. 18

Scope of Optimization (2)

- Inter-procedural (whole program)
  - entire program
  - exposes new opportunities but also new challenges
    - name-scoping
    - parameter binding
    - virtual methods
    - recursive methods (number of variables?)
  - scalability to program size

Optimization Taxonomy

Optimizations are categorized by the effect they have on the code.

- Machine independent
  - largely ignore the details of the target machine
  - in many cases profitability of a transformation depends on detailed machine-dependent issues, but those are ignored
- Machine dependent
  - explicitly consider details of the target machine
  - many of these transformations fall into the realm of code generation
  - some are within the scope of the optimizer (some cache optimizations, some expose instruction level parallelism)

Machine Independent Optimizations (1)

- Dead code elimination
  - eliminate useless or unreachable code
  - algebraic identities
- Code motion
  - move operation to place where it executes less frequently
  - loop invariant code motion, hoisting, constant propagation
- Specialize
  - to specific context in which an operation will execute
  - operator strength reduction, constant propagation, peephole optimization

Chap. 17
Chap. 18

Machine Independent Optimizations (2)

- Eliminate redundancy
  - replace redundant computation with a reference to previously computed value
  - e.g. common subexpression elimination, value numbering
- Enable other transformations
  - rearrange code to expose more opportunities for other transformations
  - e.g. inlining, cloning

Machine Dependent Optimizations

- Take advantage of special hardware features
  - Instruction Selection
- Manage or hide latency
  - Arrange final code in a way that hides the latency of some operations
  - Instruction Scheduling
- Manage bounded machine resources
  - Registers, functional units, cache memory, main memory

Case Study: C++STL Code Optimization

...on the impact of programming style and optimization on performance.

- Different programming styles for iterating on a container and performing operation on each element
- Use different levels of abstractions for iteration, container, and operation on elements
- Optimization levels O1-3 compared with GNU 4.0 compiler

Concrete example: We iterate on container 'mycontainer' and perform an operation on each element.

- Container is a `vector`
- Elements are of type `numeric_type` (`double`)
- Operation of adding 1 is applied to each element
- Evaluation Cases EC1-6

Acknowledgement: Joint work of Markus Schordan&Rene Heinzl.

Programming Styles - 1&2

EC1: Imperative Programming

```
for (unsigned int i = 0; i < mycontainer.size(); ++i)
{
     mycontainer[i] += 1.0;
}
```

EC2: Weakly Generic Programming

```
for (vector<numeric_type>::iterator
     it =  mycontainer.begin();
     it != mycontainer.end();
     ++it)
{
     *it += 1.0;
}

Programming Style - 3

EC3: Generic Programming

```
for_each(mycontainer.begin(),
         mycontainer.end(),
      plus_n<numeric_type>(1.0) );
```

Functor

```
template<class datatype>
struct plus_n
{
  plus_n(datatype member):member(member) {}
  void operator()(datatype& value) {
      value += member;
  }
private:
  datatype member;
};
```

The Essence of Program Analysis

...program analysis offers techniques for predicting statically at compile-time safe and efficient approximations to the set of configurations or behaviors arising dynamically at run-time.

- Safe: faithful to the semantics
- Efficient: implementation with
  - good time performance
  - low space consumption

Typical Optimization Aspects

- Avoid redundant computations
  - reuse available results
  - move loop invariant computations outside loops
- Avoid superfluous computations
  - results known not to be needed
  - results known already at compile time

...to be demonstrated in some examples next.

Example: Lowering, IR, Address Computation

```
int a[m][n], b[m][n], c[m][n];
...
for(int i=0; i<m; ++i) {
  for(int j=0; j<n; ++j) {
    a[i][j]=b[i][j]+c[i][j];
  }
}
```

```
i=0;
while(i<m) {
  j=0;
  while(j<n) {
    temp=Base(a)+i*n+j;
    *(temp)=*(Base(b)+i*n+j)+*(Base(c)+i*n+j);
    j=j+1;
  }
  i=i+1;
}
```

Analysis: Available Expressions Analysis

...determines for each program point, which expression must have already been computed, and not later modified, on all paths to the program point.

```
i=0;
while(i<m) {
   j=0;
   while(j<n) {
      temp = (Base(a)+i*n+j);
      *temp = *(Base(b)+ i*n+j ) + *(Base(c)+ i*n+j );
      j=j+1;
   }
   i=i+1;
}
```

Optimization: Common Subexpression Elim.

- Analysis: Available Expressions Analysis
- Transformation: Eliminate recomputations of `i*n+j`
  - Introduce `t1=i*n+j`
  - Use `t1` instead of `i*n+j`

```
i=0;
while(i<m) {
   j=0;
   while(j<n) {

      temp = (Base(a)+ i*n+j );
      *temp = *(Base(b)+ i*n+j )
            + *(Base(c)+ i*n+j );
      j=j+1;
   }
   i=i+1;
}
```

```
i=0;
while(i<m) {
   j=0;
   while(j<n) {
      t1=i*n+j ;
      temp = (Base(a)+ t1 );
      *temp = *(Base(b)+ t1 )
            + *(Base(c)+ t1 );
      j=j+1;
   }
   i=i+1;
}
```

Analysis: Loop Invariant Detection

...a loop invariant is an expression that is always computed to the same value in each iteration of the loop.

```
i=0;
while(i<m) {
   j=0;
   while(j<n) {
      t1= i*n +j;
      temp = (Base(a)+t1);
      *temp = *(Base(b)+t1) + *(Base(c)+t1);
      j=j+1;
   }
   i=i+1;
}
```

Optimization: Loop Invariant Code Motion

- Analysis: loop invariant detection
- Transformation: move loop invariant outside loop
  - introduce `t2=i*n` and replace `i*n` by `t2`
  - move `t2=i*n` outside loop

```
i=0;
while(i<m) {
   j=0;

   while(j<n) {
      t1= i*n +j;
      temp = (Base(a)+t1);
      *temp = *(Base(b)+t1)
           + *(Base(c)+t1);
      j=j+1;
   }
   i=i+1;
}
```

```
i=0;
while(i<m) {
   j=0;
   t2=i*n;
   while(j<n) {
      t1= t2 +j;
      temp = (Base(a)+t1);
      *temp = *(Base(b)+t1)
           + *(Base(c)+t1);
      j=j+1;
   }
   i=i+1;
}

Analysis: Induction Variable Detection

```
i=0;
while(i<m) {
   j=0;
   t2=i*n;
   while(j<n) {
      t1=t2+j;
      temp = (Base(a)+t1);
      *temp = *(Base(b)+t1)
            + *(Base(c)+t1);
      j=j+1;
   }
   i=i+1;
}
```

Basic Induction Variables

- Variables i whose only definitions within a loop are of the form $i = i + c$ or $i = i - c$ and c is a loop invariant.

Derived Induction Variables

- Variables j defined only once in a loop whose value is a linear function of some basic induction variable.

Optimization: Strength Reduction (1)

...replaces a repeated series of expensive ("strong") operations with a series of inexpensive ("weak") operations that compute the same values.

Classical example:

- Replacing integer multiplications based on a loop index with equivalent additions.

Note: This particular case arises routinely from expansion of array and structure addresses in loops.

Optimization: Strength Reduction (2)

- Analysis: induction variable detection
- Transformation: move multiplication outside of loop
  - introduce `t3=i*n` before the loop, replace `i*n` by `t3`
  - add `t3=t3+i*c` at every update site of `i`

```
i=0;

while(i<m) {
   j=0;
   t2=i*n;
   while(j<n) {
      t1=t2+j;
      temp = (Base(a)+t1);
      *temp = *(Base(b)+t1)
           + *(Base(c)+t1);
      j=j+1;
   }
   i=i+1;

}
```

```
i=0;
t3=0;
while(i<m) {
   j=0;
   t2= t3;
   while(j<n) {
      t1=t2+j;
      temp = (Base(a)+t1);
      *temp = *(Base(b)+t1)
           + *(Base(c)+t1);
      j=j+1;
   }
   i=i+1;
   t3=t3+n;
}

Analysis: Copy Analysis

...determines for each program point, which copy statements $x = y$ that still are relevant (i.e. neither x nor y have been redefined) when control reaches that point.

```
i=0;
t3=0;
while(i<m) {
   j=0;
   t2=t3;
   while(j<n) {
      t1=t2+j;
      temp = (Base(a)+t1);
      *temp = *(Base(b)+t1)
            + *(Base(c)+t1);
      j=j+1;
   }
   i=i+1;
   t3=t3+n;
}
```

Live Variables, Dead Variables

- A variable is live at a program point if there is a path from this program point to a use of the variable that does not re-define the variable.
- If a variable is not live, it is dead.

A live (dead) variable analysis

- determines for each program point, which variable may be live (is dead) at the exit from that point.

Pointer/Alias/Shape Analysis (1)

Problem

- Ambiguous memory references interfere with an optimizer's ability to improve code.
- One major source of ambiguity is the use of pointer-based values.

Goal of Pointer/Alias/Shape Analysis

- determine for each pointer the set of memory locations to which it may refer.

Contents

Pointer/Alias/Shape Analysis (2)

Without such analysis the compiler must assume that each pointer can refer to any addressable value, including

- any space allocated in the run-time heap
- any variable whose address is explicitly taken
- any variable passed as a call-by-reference parameter

Forms of Pointer Analysis

- points-to sets
- alias pairs
- shape analysis

Questions about Heap Contents (1)

Let execution state mean the set of cells in the heap, the connections between them (via pointer components of heap cells) and the values of pointer variables in the store.

- NULL pointers: Does a pointer variable or a pointer component of a heap cell contain NULL at the entry to a statement that dereferences the pointer or component?
  - Yes (for every state). Issue an error message.
  - No (for every state). Eliminate a check for NULL.
  - Maybe. Warn about the potential NULL dereference.
- Memory leak: Does a procedure or a program leave behind unreachable heap cells when it returns?
  - Yes (in some state). Issue a warning.

Questions about Heap Contents (2)

- Aliasing: Do two pointer expressions reference the same heap cell?
  - Yes (for every state).
    - trigger a prefetch to improve cache performance
    - predict a cache hit to improve cache behavior prediction
    - increase the sets of uses and definitions for an improved liveness analysis
  - No (for every state). Disambiguate memory references and improve program dependence information.
- Sharing: Is a heap cell shared? (within the heap)
  - Yes (for some state). Warn about explicit deallocation, because the memory manager may run into an inconsistent state.
  - No (for every state). Explicitly deallocate the heap cell when the last pointer to ceases to exist.

Questions about Heap Contents (3)

- Reachability: Is a heap cell reachable from a specific variable or from any pointer variable?
  - Yes (for every state). Use this information for program verification.
  - No (for every state). Insert code at compile time that collects unreachable cells at run-time.
- Disjointness: Do two data structures pointed to by two distinct pointer variables ever have common elements?
  - No (for every state). Distribute disjoint data structures and their computations to different processors.
- Cyclicity: Is a heap cell part of a cycle?
  - No (for every state). Perform garbage collection of data structures by reference counting. Process all elements in an acyclic linked list in a doall-parallel fashion.

Optimizations f. Object-Oriented Languages (1)

Invoking a method in an object-oriented language requires looking up the address of the block of code which implements that method and passing control to it.

Opportunities for optimization

- Look-up may be performed at compile time
- Only one implementation of the method in the class and in its subclasses
- Language provides a declaration which forces the call to be non-virtual
- Compiler performs static analysis which can determine that a unique implementation is always called at a particular call-site.

Typical Questions

...of program analysis, especially data flow analysis:

- What is the value of a variable at a program point?
  $\rightsquigarrow$ Constant progagation and folding
- Is the value of an expression available at a program point?
  $\rightsquigarrow$ (Partial) redundancy elimination
- Is a variable dead at a program point?
  $\rightsquigarrow$ Elimination of (partially) dead code

Essential Issues

comprise...

fundamental ones

- What does optimality mean?
  ...in analysis and optimization?

as (apparently) minor ones:

- What is an appropriate and suitable program representation?

Outlook (cont'd)

Ingredients of (intraprocedural) data flow analysis:

- (Local) abstract semantics
  1. A data flow analysis lattice $\hat{\mathcal{C}} = (\mathcal{C}, \sqcap, \sqcup, \sqsubseteq, \bot, \top)$
  2. A data flow analysis functional $[\![\ ]\!] : E \to (\mathcal{C} \to \mathcal{C})$
  3. A Start information (start assertion) $c_s \in \mathcal{C}$
- Globalization strategies
  1. "Meet over all Paths" Approach (*MOP*)
  2. Maximum Fixed Point Approach (*MaxFP*)
- Generic Fixed Point Algorithm

Formalising the Development

- the programming language of interest
  - abstract syntax
  - labelled program fragments
- abstract flow graphs
  - control and data flow between labelled program fragments
- extract equations from the program
  - specify the information to be computed at entry and exit of labeled fragments
- compute the solution to the equations
  - work list algorithms
  - compute entry and exit information at entry and exit of labelled fragments

Abstract Syntax

$$
\begin{array}{lcl}
a & ::= & x \mid n \mid a_1 \; op_a \; a_2 \\
b & ::= & \text{true} \mid \text{false} \mid \text{not } b \mid b_1 \; op_b \; b_2 \mid a_1 \; op_r \; a_2 \\
S & ::= & [\text{x:=a}]^\ell \mid [\text{skip}]^\ell \\
 & & \mid \text{if } [b]^\ell \text{ then } S_1 \text{ else } S_2 \\
 & & \mid \text{while}[b]^\ell \text{ do } S \text{ od} \\
 & & \mid S_1; S_2
\end{array}
$$

Assignments and tests are (uniquely) labelled to allow analyses to refer to these program fragments – the labels correspond to pointers into the syntax tree. We use abstract syntax and insert paranthesis to disambiguate syntax.

We will often refer to labelled fragments as elementary blocks.

Auxiliary Functions for Flow Graphs

labels(S)	set of nodes of flow graphs of S
init(S)	initial node of flow graph of S; the unique node where execution of program starts
final(S)	final nodes of flow graph for S; set of nodes where program execution may terminate
flow(S)	edges of flow graphs for S (used for forward analyses)
flow^R(S)	reverse edges of flow graphs for S (used for backward analyses)
blocks(S)	set of elementary blocks in a flow graph

Program of Interest (1)

We shall use the following notation:

- $S_\star$ to represent the program being analyzed (the "top level" statement)
- $\mathrm{Lab}_\star$ to represent the labels ($\mathrm{labels}(S_\star)$) appearing in $S_\star$
- $\mathrm{Var}_\star$ to represent the variables ($\mathrm{FV}(S_\star)$) appearing in $S_\star$
- $\mathrm{Blocks}_\star$ to represent the elementary blocks ($\mathrm{blocks}(S_\star)$) occuring in $S_\star$
- $\mathrm{AExp}_\star$ to represent the set of *non-trivial* arithmetic subexpressions in $S_\star$; an expression is trivial if it is a single variable or constant
- $\mathrm{AExp}(a)$, $\mathrm{AExp}(b)$ to refer to the set of non-trivial arithmetic subexpressions of a given arithmetic, respectively boolean, expression

Program of Interest (2)

Free Variables FV(a)

The free variables of an arithmetic expression, $a \in \mathsf{AExp}$, are defined to be variables occuring in it.

Compositional definition of subset FV(a) of Var

$$
\begin{aligned}
\mathsf{FV}(n) &= \emptyset \\
\mathsf{FV}(x) &= \{x\} \\
\mathsf{FV}(a_1 + a_2) &= \mathsf{FV}(a_1) \cup \mathsf{FV}(a_2) \\
\mathsf{FV}(a_1 \star a_2) &= \mathsf{FV}(a_1) \cup \mathsf{FV}(a_2) \\
\mathsf{FV}(a_1 - a_2) &= \mathsf{FV}(a_1) \cup \mathsf{FV}(a_2)
\end{aligned}
$$

Similarly for boolean expressions, $b \in \mathsf{BExp}$, and statements, $S \in \mathsf{Stmt}$, such that $\mathsf{Var}_\star = \mathsf{FV}(S_\star)$.

Simplifying Assumptions

The program of interest $S_\star$ is often assumed to satisfy:

- $S_\star$ has isolated entries if there are no edges leading into $\mathsf{init}(S_\star)$:
$$\forall \ell : (\ell, \mathsf{init}(S_\star)) \notin \mathsf{flow}(S_\star)$$
- $S_\star$ has isolated exits if there are no edges leading out of labels in $\mathsf{final}(S_\star)$:
$$\forall \ell \in \mathsf{final}(S_\star), \forall \ell' : (\ell, \ell') \notin \mathsf{flow}(S_\star)$$
- $S_\star$ is label consistent if
$$\forall B_1^{\ell_1}, B_2^{\ell_2} \in \mathsf{blocks}(S_\star) : \ell_1 = \ell_2 \rightarrow B_1 = B_2$$

This holds if $S_\star$ is uniquely labelled.

Reaching Definitions Analysis

...determines for each program point, which assignments may have been made and not overwritten, when program execution reaches this point along some path.

Example:

$[y := x]^1; [z := 1]^2; \text{while } [y > 1]^3 \text{ do } [z := z * y]^4; [y := y - 1]^5 \text{ od}; [y := 0]^6$

- The assignments labelled 1,2,4,5 reach the entry at 4.
- Only the assignments labelled 1,4,5 reach the entry at 5.

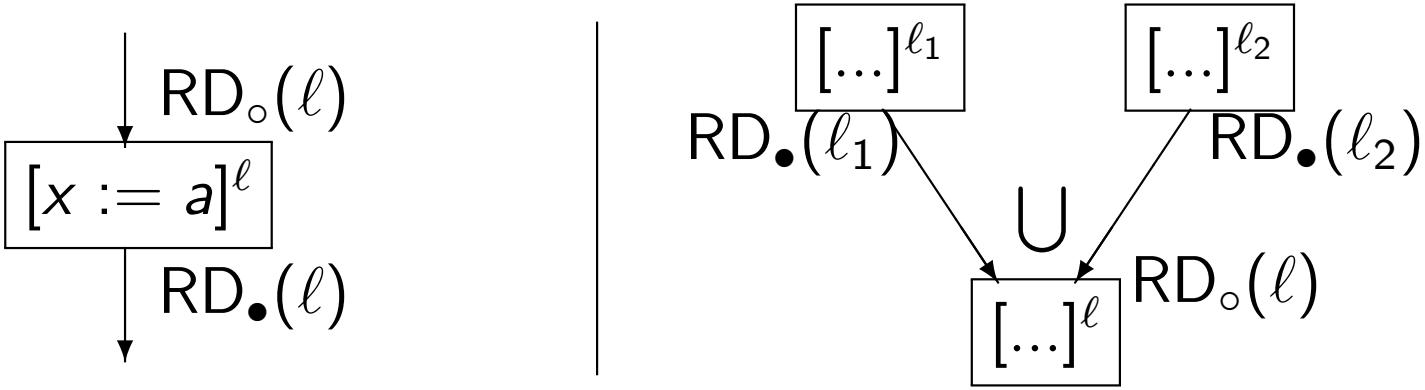
Basic Idea



Analysis information: $\mathsf{RD}_\circ(\ell), \mathsf{RD}_\bullet(\ell) : \mathsf{Lab}_\star \to \mathcal{P}\mathsf{Var}_\star \times \mathsf{Lab}_\star^?$

- $\mathsf{RD}_\circ(\ell)$: the definitions that reach entry of block ℓ.
- $\mathsf{RD}_\bullet(\ell)$: the definitions that reach exit of block ℓ.

Analysis properties:

- Direction: forward
- May analysis with combination operator $\bigcup$

Solving RD Equations

Input

- a set of reaching definitions equations

Output

- the least solution to the equations: $\mathrm{RD}_\circ$

Data structures

- The current analysis result for block entries: $\mathrm{RD}_\circ$
- The worklist W: a list of pairs (ℓ, ℓ') indicating that the current analysis result has changed at the entry to the block ℓ and hence the information must be recomputed for ℓ'.

Use-Definition and Definition-Use Chains

- Use-Definition chains or *ud* chains

  each use of a variable is linked to all assignments that *reach* it

  $[x := 0]^1; [x := 5]^2; [y := x]^3; [z := x]^4$

- Definition-Use chains or *du* chains

  each assignment of a variable is linked to all uses of it

  $[x := 0]^1; [x := 5]^2; [y := x]^3; [z := x]^4$

UD/DU Chains – Defined via RDs

$$\mathsf{UD},\mathsf{DU} : \mathsf{Var}_\star \times \mathsf{Lab}_\star \to \mathcal{P}(\mathsf{Lab}_\star)$$

are defined by

$$\mathsf{UD}(x,\ell) = \begin{cases} \{\ell' \mid (x,\ell') \in \mathsf{RD}_\circ(\ell)\} & : \quad \text{if } x \in \mathsf{used}(B^\ell) \\ \emptyset & : \quad \text{otherwise} \end{cases}$$

where $\mathsf{used}([x := a]^\ell) = \mathsf{FV}(a)$, $\mathsf{used}([b]^\ell) = \mathsf{FV}(b)$, $\mathsf{used}([\mathsf{skip}]^\ell) = \emptyset$

and

$$\mathsf{DU}(x,\ell) = \{\ell' \mid \ell \in \mathsf{UD}(x,\ell')\}$$

Available Expressions Analysis

...determines for each program point, which expressions must have already been computed, and not later modified, on all paths to the program point.

Example:

$[x := a+b]^1; [y := a*x]^2; \text{while } [y > a+b]^3 \text{ do } [a := a + 1]^4; [x := a + b]^5 \text{ od}$

- No expression is available at the start of the program.
- An expression is considered available if no path kills it.
- The expression a+b is available every time execution reaches the test in the loop at 3.

Solving AE Equations

Input

- a set of available expressions equations

Output

- the largest solution to the equations: $\mathsf{AE}_\circ$

Data structures

- The current analysis result for block entries: $\mathsf{AE}_\circ$
- The worklist W: a list of pairs (ℓ, ℓ') indicating that the current analysis result has changed at the entry to the block ℓ and hence the information must be recomputed for ℓ'.

Common Subexpression Elimination (CSE)

...aims at finding computations that are always performed at least twice on a given execution path and to eliminate the second and later occurrences; it uses Available Expressions Analysis to determine the redundant computations.

Example:

$[x := a+b]^1; [y := a*x]^2; \text{while } [y > a+b]^3 \text{ do } [a := a + 1]^4; [x := a + b]^5 \text{ od}$

- Expression a+b is computed at 1 and 5 and recomputation can be eliminated at 3.

The Optimization – CSE

Let $S_\star^N$ be the normalized form of $S_\star$ such that there is at most one operator on the right hand side of an assignment.

For each $[\ldots a \ldots]^\ell$ in $S_\star^N$ with $a \in \mathrm{AE}_\circ(\ell)$ do

- determine the set $\{[y_1 := a]^{\ell_1}, \ldots, [y_k := a]^{\ell_k}\}$ of elementary blocks in $S_\star^N$ "defining" a that reaches $[\ldots a \ldots]^\ell$
- create a fresh variable u and
  - replace each occurrence of $[y_i := a]^{\ell_i}$ with $[u := a]^{\ell_i}; [y_i := u]^{\ell'_i}$ for $1 \leq i \leq k$
  - replace $[\ldots a \ldots]^\ell$ with $[\ldots u \ldots]^\ell$

$[x := a]^{\ell'}$ reaches $[\ldots a \ldots]^\ell$ if there is a path in $\mathrm{flow}(S_\star^N)$ from ℓ' to ℓ that does not contain *any* assignments with expression a on the right hand side and no variable of a is modified.

Computing the "reaches" Information

$[x := a]^{\ell'}$ reaches $[\ldots a \ldots]^{\ell}$ if there is a path in $\text{flow}(S_\star^N)$ from ℓ' to ℓ that does not contain any assignments with expression a on the right hand side and no variable of a is modified.

The set of elementary blocks that reaches $[\ldots a \ldots]^{\ell}$ can be computed as $\text{reaches}_\circ(a, \ell)$ where

$$\text{reaches}_\circ(a, \ell) = \begin{cases} \emptyset & : \text{ if } \ell = \text{init}(S_\star) \\ \bigcup \text{reaches}_\bullet(a, \ell') & : \text{ otherwise} \end{cases}$$

$$\text{reaches}_\bullet(a, \ell) = \begin{cases} \{B^\ell\} & : \text{ if } B^\ell \text{ has the form} [x := a]^\ell \text{ and } x \notin \text{FV}(a) \\ \emptyset & : \text{ if } B^\ell \text{ has the form} [x := \ldots]^\ell \text{ and } x \in \text{FV}(a) \\ \text{reaches}_\circ(a, \ell) & : \text{ otherwise} \end{cases}$$

Copy Propagation (CP) (1)

...aims at finding copy statements $[x := y]^{\ell_j}$ and eliminating them if possible.

If x is used in $B^{\ell'}$ then x can be replaced by y in $B^{\ell'}$ provided that

- $[x := y]^{\ell_j}$ is the only kind of definition of x that reaches $B^{\ell'}$ – this information can be obtained from the def-use chain.
- on every path from ℓ_j to ℓ' (including paths going through ℓ' several times but only once through ℓ_j) there are no redefinitions of y; this can be detected by Copy Analysis.

The Optimization – CP

For each copy statement $[x := y]^{\ell_j}$ in $S_\star$ do

- determine the set $\{[...x...]^{\ell_1}, ..., [...x...]^{\ell_i}\}$,$1 \leq i \leq k$, of elementary blocks in $S_\star$ that uses $[x := y]^{\ell_j}$ – this can be computed from DU(x,ℓ_j)
- for each $[...x...]^{\ell_i}$ in this set determine whether $\{(x', y') \in \mathrm{C}_\circ(\ell_i) \mid x' = x\} = \{(x, y)\}$; if so then $[x := y]$ is the only kind of definition of x that reaches ℓ_i from all ℓ_j.
- if this holds for all i $(1 \leq i \leq k)$ then
  - remove $[x := y]^{\ell_j}$
  - replace $[...x...]^{\ell_i}$ with $[...y...]^{\ell_i}$ for $1 \leq i \leq k$.

Live Variable Analysis

Definition Live Variables

A variable is live at the exit from a label if there is a path from the label to a use of the variable that does not re-define the variable.

The Aim of the Live Variables Analysis is to

determine for each program point, which variables may be live at the exit from the point.

Example

$[y := 0]^0; [u := a+b]^1; [y := a*u]^2; \text{while } [y > u]^3 \text{ do } [a := a + 1]^4; [u := a + b]^5; [x := u]^6 \text{ od}$

- y is dead (i.e., not live) at the exit from label 0
- x is dead (i.e., not live) at the exit from label 6

Dead Code Elimination (DCE)

An assignment $[x := a]^\ell$ is dead if the value of x is not used before it is redefined. Dead assignments can be eliminated.

- Analysis: Live Variables Analysis
- Transformation: For each $[x := a]^\ell$ in $S_\star$ with $x \notin \mathsf{LV}_\bullet(\ell)$ (i.e. dead) eliminate $[x := a]^\ell$ from the program.

Example:

Before DCE:

$[\mathsf{y} := 0]^0; [\mathsf{u} := \mathsf{a}+\mathsf{b}]^1; [\mathsf{y} := \mathsf{a}*\mathsf{u}]^2; \mathsf{while}\ [\mathsf{y} > \mathsf{u}]^3\ \mathsf{do}\ [\mathsf{a} := \mathsf{a} + 1]^4; [\mathsf{u} := \mathsf{a} + \mathsf{b}]^5; [\mathsf{x} := \mathsf{u}]^6\ \mathsf{od}$

After DCE:

$[\mathsf{u} := \mathsf{a}+\mathsf{b}]^1; [\mathsf{y} := \mathsf{a}*\mathsf{u}]^2; \mathsf{while}\ [\mathsf{y} > \mathsf{u}]^3\ \mathsf{do}\ [\mathsf{a} := \mathsf{a} + 1]^4; [\mathsf{u} := \mathsf{a} + \mathsf{b}]^5;\ \mathsf{od}$

Combining Optimizations

...usually strengthens the overall impact.

Example:

$[x := a+b]^1; [y := a*x]^2; \text{while } [y > a+b]^3 \text{ do } [a := a + 1]^4; [x := a + b]^5 \text{ od}$

1. Common Subexpression Elimination gives

$[u := a+b]^{1'}; [x := u]^1; [y := a*x]^2; \text{while } [y > u]^3 \text{ do } [a := a + 1]^4; [u := a + b]^{5'}; [x := u]^5 \text{ od}$

2. Copy Propagation gives

$[u := a+b]^{1'}; [y := a*u]^2; \text{while } [y > u]^3 \text{ do } [a := a + 1]^4; [u := a + b]^{5'}; [x := u]^5 \text{ od}$

3. Dead Code Elimination gives

$[u := a+b]^1; [y := a*u]^2; \text{while } [y > u]^3 \text{ do } [a := a + 1]^4; [u := a + b]^5; \text{ od}$

What are the results for other optimization sequences?

Faint Variables

...generalize the notion of dead variables.

Consider the following program consisting of three statements:

$[\mathsf{x} := 1]^1; [\mathsf{x} := 2]^2; [\mathsf{y} := \mathsf{x}]^3;$

Clearly x is dead at the exit from 1 and y is dead at the exit of 3. But x is live at the exit of 2 although it is only used to calculate a new value for y that turns out to be dead.

We shall say that a variable is a faint variable if it is dead or if it is only used to calculate new values for faint variables; otherwise it is strongly live.

Very Busy Expressions Analysis

Definition Very Busy Expressions

An expression is very busy at the exit from a label if, no matter what path is taken from the label, the expression is always used before any of the variables occurring in it are redefined.

The Aim of the Very Busy Expression Analysis is to

determine for each program point, which expressions must be very busy at the exit from the point.

Example

if $[a > b]^1$ then $([x := b-a]^2; [y := a-b]^3)$ else $([y := b-a]^4; [x := a-b]^5)$

- b-a and a-b are very busy at the exit from label 1

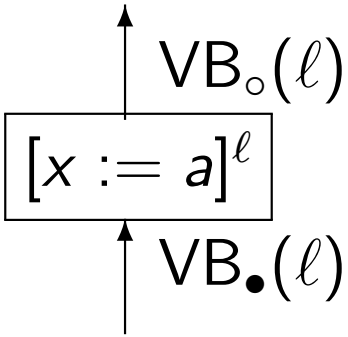
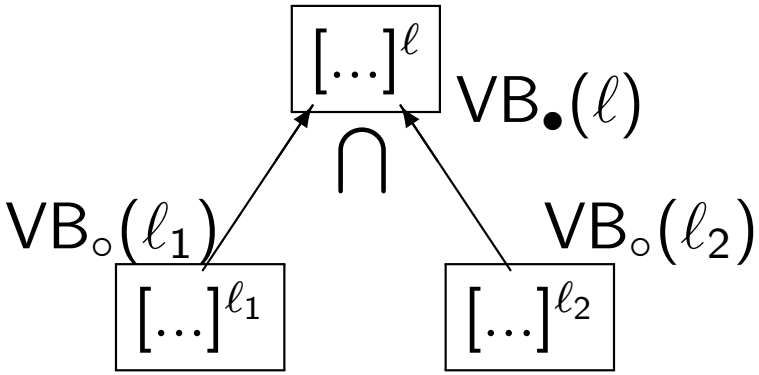
Basic Idea





Analysis information: $\mathsf{VB}_\circ(\ell)$,$\mathsf{VB}_\bullet(\ell)$: $\mathsf{Lab}_\star \to \mathcal{P}\mathsf{AExp}_\star$

- $\mathsf{VB}_\circ(\ell)$: the expressions that are very busy at entry of block ℓ.
- $\mathsf{VB}_\bullet(\ell)$: the expressions that are very busy at exit of block ℓ.

Analysis properties:

- Direction: backward
- Must analysis with combination operator $\bigcap$

Code Hoisting (CH)

...finds expressions that are always evaluated following some point in the program regardless of the execution path – and moves them to the earliest point (in execution order) beyond which they would always be executed.

Example:

Before CH:

$\text{if } [a > b]^1 \text{ then } ([x := b-a]^2; [y := a-b]^3) \text{ else } ([y := b-a]^4; [x := a-b]^5)$

After CH:

$[t1 := a-b]^0; [t2 := b-a]^{0'};$
$\text{if } [a > b]^1 \text{ then } ([x := t2]^2; [y := t1]^3) \text{ else } ([y := t2]^4; [x := t1]^5)$

Bit Vectors and Bit Vector Analyses

The classical analyses operate over elements of $\mathcal{P}(D)$ where D is a finite set.

The elements can be represented as bit vectors. Each element of D can be assigned a unique bit position i ($1 \leq i \leq n$). A subset S of D is then represented by a vector of n bits:

- if the i'th element of D is in S then the i'th bit is 1.
- if the i'th element of D is not in S then the i'th bit is 0.

Then we have efficient implementations of

- set union as logical 'or'
- set intersection as logical 'and'

More Bit Vector Framework Examples

- Dual available expressions determines for each program point which expressions may not be available when execution reaches that point (forward may analysis)
- Copy analysis determines whether there on every execution path from a copy statement $x := y$ to a use of x there are no assignments to y (forward must analysis).
- Dominators determines for each program point which program points are guaranteed to have been executed before the current one is reached (forward must analysis).
- Upwards exposed uses determines for a program point, what uses of a variable are reached by a particular definition (assignment) (backward may analysis).

Some Non-Bit Vector Framework Examples (1)

- Constant propagation determines for each program point whether or not a variable has a constant value whenever execution reaches that point (forward must analysis).
- Detection of signs analysis determines for each program point the possible signs that the values of the variables may have whenever execution reaches that point (forward must analysis).
- Faint variables determines for each program point which variables are faint: a variable is faint if it is dead or it is only used to compute new values of faint variables (backward must analysis).

Flow Graphs

A (non-deterministic) flow graph is a tuple $G = (N, E, s, e)$ with

- node set N
- edge set $E \subseteq N \times N$
- distinguished start node s w/out any predecessors
- distinguished end node e w/out successors

Nodes represent program points, edges represent the branching structure. Program statements (assignments, tests) can be represented by

- nodes: node-labelled flow graph
- edges: edge-labelled flow graph

where nodes and edges are labelled by single instructions or basic blocks, respectively.

Summing up

We distinguish:

- Node-labelled flow graphs
  - Single instruction graphs (SI graphs)
  - Basic block graphs (BB graphs)
- Edge-labelled flow graphs
  - Single instruction graphs (SI graphs)
  - Basic block graphs (BB graphs)

Later on we will preferably deal w/ edge-labelled SI graphs.

Notations

Let $G = (N, E, s, e)$ be a flow graph, let m, n be two nodes of N. Then:

- $\mathbf{P}_G[m, n]$ denotes the set of all paths from m to n (including m and n)
- $\mathbf{P}_G[m, n[$ denotes the set of all paths from m to a predecessor of n
- $\mathbf{P}_G]m, n]$ denotes the set of all paths from a successor of m to n
- $\mathbf{P}_G]m, n[$ denotes the set of all paths from a successor of m to a predecessor of n

Note: If G is uniquely determined by the context, then we drop the index and simply write $\mathbf{P}$ instead of $\mathbf{P}_G$.

DFA Specification, DFA Problem

Definition (5.1, DFA Specification)

A DFA specification is given by

- a (local) abstract semantics consisting of
  1. a DFA lattice $\hat{\mathcal{C}} = (\mathcal{C}, \sqcap, \sqcup, \sqsubseteq, \bot, \top)$
  2. a DFA functional $[\![\ ]\!] : E \to (\mathcal{C} \to \mathcal{C})$
- a start information/assertion: $c_s \in \mathcal{C}$

Definition (5.2, DFA Problem)

A DFA specification defines a DFA problem.

Properties

...of DFA functionals, DFA problems:

Definition (5.3)

A DFA functional $[\![\ ]\!] : E \to (\mathcal{C} \to \mathcal{C})$ is monotonic/distributive/additive iff for all $e \in E$ the local semantic function $[\![\ e\ ]\!]$ is monotonic/distributive/additive.

Definition (5.4)

A DFA problem is monotonic/distributive/additive iff the DFA functional $[\![\ ]\!]$ of the underlying DFA specification $(\hat{\mathcal{C}}, [\![\ ]\!], c_s)$ is monotonic/distributive/additive.

These properties induce a taxonomy of DFA problems.

Monotonicity, Distributivity, Additivity (1)

Definition (5.5, Properties of DFA Functionals)

Let $\hat{\mathcal{C}} = (\mathcal{C}, \sqcap, \sqcup, \sqsubseteq, \bot, \top)$ be a complete (DFA) lattice and $f : \mathcal{C} \to \mathcal{C}$ a function on $\mathcal{C}$. Then f is

1. monotonic iff $\forall\, c, c' \in \mathcal{C}.\ c \sqsubseteq c' \Rightarrow f(c) \sqsubseteq f(c')$
   (Preservation of the order of elements)
2. distributive iff $\forall\, C' \subseteq \mathcal{C}.\ \ f(\bigsqcap C') = \bigsqcap \{f(c) \mid c \in C'\}$
   (Preservation of greatest lower bounds)
3. additive gdw $\forall\, C' \subseteq \mathcal{C}.\ \ f(\bigsqcup C') = \bigsqcup \{f(c) \mid c \in C'\}$
   (Preservation of least upper bounds)

Monotonicity vs. Distributivity and Additivity

We have:

Lemma (5.6)

Let $\hat{\mathcal{C}} = (\mathcal{C}, \sqcap, \sqcup, \sqsubseteq, \bot, \top)$ *be a complete (DFA) lattice and* $f : \mathcal{C} \to \mathcal{C}$ *a function on* $\mathcal{C}$*. Then:*

$$
\begin{aligned}
f \text{ is monotonic} &\iff \forall\, C' \subseteq \mathcal{C}.\ f(\bigsqcap C') \sqsubseteq \bigsqcap \{f(c) \mid c \in C'\} \\
&\iff \forall\, C' \subseteq \mathcal{C}.\ f(\bigsqcup C') \sqsupseteq \bigsqcup \{f(c) \mid c \in C'\}
\end{aligned}
$$

Chain Condition

Definition (5.7 Chain Condition)

A (DFA) lattice $\hat{\mathcal{C}} = (\mathcal{C}, \sqcap, \sqcup, \sqsubseteq, \bot, \top)$ satisfies the

1. descending chain condition, if every descending chain gets stationary, i.e. for each chain $c_1 \sqsupseteq c_2 \sqsupseteq \ldots \sqsupseteq c_n \sqsupseteq \ldots$ there is an index $m \geq 1$ such that $c_m = c_{m+j}$ holds for all $j \in \mathbb{N}$
2. ascending chain condition, if every ascending chain gets stationary, i.e. for each chain $c_1 \sqsubseteq c_2 \sqsubseteq \ldots \sqsubseteq c_n \sqsubseteq \ldots$ there is an index $m \geq 1$ such that $c_m = c_{m+j}$ holds for all $j \in \mathbb{N}$

Next Step

...globalizing a local abstract semantics from statements to flow graphs.

For that we introduce two (globalization) strategies:

- Meet over all Paths Approach (*MOP*)
  $\rightsquigarrow$ yields the specifying solution of a DFA problem
- Maximum Fixed Point (*MaxFP*) Approach
  $\rightsquigarrow$ yields a computable solution of a DFA problem

The *MOP* Approach

Essential for the *MOP* approach:

Definition (5.1.1, Path extension of $[\![\ ]\!]$)

The extension of a local abstract semantics $[\![\ ]\!]$ onto paths $p = \langle e_1, e_2 \ldots, e_q \rangle$ is defined by

$$[\![\, p \,]\!] =_{df} \begin{cases} Id_{\mathcal{C}} & \text{falls } q < 1 \\ [\![\, \langle e_2, \ldots, e_q \rangle \,]\!] \circ [\![\, e_1 \,]\!] & \text{otherwise} \end{cases}$$

where $Id_{\mathcal{C}}$ denotes the identity on $\mathcal{C}$.

Chap. 14

The *MOP* Solution

Definition (5.1.2, *MOP* Solution)

Let $(\hat{\mathcal{C}}, [\![\ ]\!], c_{\mathbf{s}})$ be the specification of a DFA problem. Then, for all nodes $n \in N$ the *MOP* solution is defined by:

$$MOP_{(\hat{\mathcal{C}},[\![\ ]\!],c_{\mathbf{s}})}(n) = \bigsqcap \{\, [\![\, p \,]\!](c_{\mathbf{s}}) \mid p \in \mathbf{P}[\mathbf{s}, n] \,\}$$

Essential:

- The *MOP* solution is considered the specifying solution of the DFA problem given by $(\hat{\mathcal{C}}, [\![\ ]\!], c_{\mathbf{s}})$.

Unfortunately

...the following negative result holds:

Theorem (5.1.1, Undecidabality)

There is no algorithm A satisfying:

- *The input of A are*
  - *algorithms for the computation of the meet, the equality test, and the application of functions on the lattice elements of a monotonic DFA framework*
  - *a DFA problem p specified by an instance of a DFA specification* $(\mathcal{C}, [\![\ \ ]\!], c_{\mathsf{s}})$
- *The output of A is the MOP solution of p.*

The *MaxFP* Approach

Essential for the *MaxFP* approach:

Definition (5.2.1, *MaxFP* Equation System)

The *MaxFP* equation system is given by:

$$inf(n) = \begin{cases} c_{\mathbf{s}} & \text{if } n = \mathbf{s} \\ \bigsqcap \{ [\![(m,n)]\!](inf(m)) \mid m \in pred(n) \} & \text{otherwise} \end{cases}$$

Chap. 14

The *MaxFP* Solution

Definition (5.2.2, *MaxFP* Solution)

Let $(\hat{\mathcal{C}}, [\![\ ]\!], c_s)$ be the specification of a DFA problem. Then, for all nodes $n \in N$ the *MaxFP* solution is defined by:

$$MaxFP_{(\hat{\mathcal{C}},[\![\ ]\!],c_s)}(n) =_{df} inf^*_{c_s}(n)$$

where $inf^*_{c_s}$ denotes the greatest solution of the *MaxFP* Equation System 5.2.1 wrth $(\hat{\mathcal{C}}, [\![\ ]\!], c_s)$.

Essential:

- The *MaxFP* solution is effectively computable under the conditions of the Termination Theorem 5.2.4). It is thus considered the computable solution of a DFA problem.

The Generic Fixed Point Algorithm 5.2.3 (1)

Input: (1) A flow graph $G = (N, E, \mathbf{s}, \mathbf{e})$, (2) a DFA problem given by a (local) abstract semantics consisting of a DFA lattice $\mathcal{C}$, a DFA functional $[\![\ ]\!] : E \to (\mathcal{C} \to \mathcal{C})$, and (3) a start information $c_{\mathbf{s}} \in \mathcal{C}$.

Output: The *MaxFP* solution, if the preconditions of the Termination Theorem 5.2.4 hold. Depending on the properties of the DFA functional we have:
(i) $[\![\ ]\!]$ is distributive: The variable *inf* stores for each node the strongest post-condition wrt the start information $c_{\mathbf{s}}$.
(ii) $[\![\ ]\!]$ is monotonic: The variable *inf* stores for each node a safe (i.e. lower) approximation of the strongest post-condition wrt the start information $c_{\mathbf{s}}$.

Remark: The variable *workset* controls the iterative process. Its elements are nodes of G, whose annotation has recently been updated.

Effectivity

Theorem (5.2.4, Termination)

The Generic Fixed Point Algorithm 5.2.3 terminates with the $MaxFP_{(\hat{\mathcal{C}},[\![\ ]\!],c_s)}$ *solution, if*

a) *the DFA functional* $[\![\ ]\!]$ *is monotonic*

b) *the DFA lattice* $\hat{\mathcal{C}}$ *satisfies the descending chain condition.*

Note

The Generic Fixed Point Algorithm 5.2.3 is formulated for

- universally quantified ("distributive") forward problems

The other three variants of DFA problems of

- existentially quantified ("additive") problems
- backward problems

can be captured and solved with the Generic Fixed Point Algorithm 5.2.3 by "turning round"

- the lattice (by replacing of $\sqsubset$ by $\sqsupset$)
- the flow graph (by reversing all edges)

Main Results: Soundness and Completeness

The relationship of *MOP* and *MaxFP* solution

- Soundness
- Completeness

In Detail:

- Soundness:
  Does always hold $MaxFP_{(\hat{\mathcal{C}},[\![\ ]\!],c_s)} \sqsubseteq MOP_{(\hat{\mathcal{C}},[\![\ ]\!],c_s)}$?
- Completeness:
  Does always hold $MaxFP_{(\hat{\mathcal{C}},[\![\ ]\!],c_s)} \sqsupseteq MOP_{(\hat{\mathcal{C}},[\![\ ]\!],c_s)}$?

Notations

- $\hat{\mathbb{B}} =_{df} (\mathbb{B}, \wedge, \vee, \leq, \textbf{false}, \textbf{true})$: The lattice of Boolean values w/ **false** $\leq$ **true** and the logical $\wedge$ and $\vee$ as meet operation and join operation $\sqcap$ and $\sqcup$, respectively.
- $Cst_{\textbf{true}}$ and $Cst_{\textbf{false}}$: The constant functions "true" and "false" on $\hat{\mathbb{B}}$, respectively.
- $Id_{\mathbb{B}}$: The identity function on $\hat{\mathbb{B}}$.

...and for a fixed candidate expression t:

- $Comp_e$: t is computed by the instruction attached to edge e (i.e., t is a subexpression of the right-hand side expression)
- $Transp_e$: no operand of t is assigned a new value by the instruction attached to edge e (i.e. no operand of t occurs on the left-hand side: e is transparent for t)

Abstract Semantics for Simple Constants

- Local abstract semantics for simple constants:
  1. DFA lattice: $(\mathcal{C}, \sqcap, \sqcup, \sqsubseteq, \bot, \top) =_{df} (\Sigma, \sqcap, \sqcup, \sqsubseteq, \sigma_\bot, \sigma_\top)$
  2. DFA functional: $[\![\ ]\!]_{sc} : E \to (\Sigma \to \Sigma)$ defined by

$$\forall\, e \in E.\ [\![\, e \,]\!]_{sc} =_{df} \theta_e$$

The Semantics of Terms

The semantics of terms $t \in \mathbf{T}$ is given by the inductively defined evaluation function

$$\mathcal{E} : \mathbf{T} \to (\Sigma \to \mathbf{D})$$

$$\forall t \in \mathbf{T}\, \forall \sigma \in \Sigma.\, \mathcal{E}(t)(\sigma) =_{df} \begin{cases} \sigma(x) & \text{if } t = x \in \mathbf{V} \\ I_0(c) & \text{if } t = c \in \mathbf{C} \\ I_0(op)(\mathcal{E}(t_1)(\sigma), \ldots, \mathcal{E}(t_r)(\sigma)) & \\ & \text{if } t = op(t_1, \ldots, t_r) \end{cases}$$

The Syntax of Terms (1)

Let

- **V** be a set of variables
- **Op** be a set of n-ary operators, $n \geq 0$, and $\mathbf{C} \subseteq \mathbf{Op}$ be the set of 0-ary operators, the so-called constants in **Op**.

Chap. 11
Chap. 12
Chap. 13
Chap. 14

The Syntax of Terms (2)

We legen fest:

1. Each variable $v \in \mathbf{V}$ and each constant $c \in \mathbf{C}$ is a term.
2. If $op \in \mathbf{Op}$ is an n-ary operator, $n \geq 1$, and $t_1, \ldots, t_n$ are terms, then $op(t_1, \ldots, t_n)$ is a term, too.
3. There are no other terms in addition to those that can be constructed by the above two rules.

The set of all terms is denoted by $\mathbf{T}$.

Interpretation

Let $\mathbf{D}'$ be a suitable data domain (e.g. the set of integers), let $\perp$ and $\top$ be two distinguished elements w/ $\perp, \top \notin \mathbf{D}'$, and let $\mathbf{D} =_{df} \mathbf{D}' \cup \{\perp, \top\}$.

An interpretation on $\mathbf{T}$ and $\mathbf{D}$ is a tuple $I \equiv (\mathbf{D}, I_0)$, where

- I_0 is a function, which associates w/ each 0-ary operator $c \in \mathbf{Op}$ a datum $I_0(c) \in \mathbf{D}'$ and w/ each n-ary operator $op \in \mathbf{Op}$, $n \geq 1$, a total function $I_0(op) : \mathbf{D}^n \to \mathbf{D}$, which is assumed to be strict (i.e. $I_0(op)(d_1, \ldots, d_n) = \perp$, if there is a $j \in \{1, \ldots, n\}$ w/ $d_j = \perp$)

Set of States

$$\Sigma =_{df} \{ \sigma \mid \sigma : \mathbf{V} \to \mathbf{D} \}$$

...denotes the set of states, i.e. the set of mappings σ from the set of variables $\mathbf{V}$ to a suitable data domain $\mathbf{D}$ (that is not specified in more detail here).

In particular

- $\sigma_\perp$: ...denotes the totally undefined state of Σ that is defined as follows: $\forall\, v \in \mathbf{V}.\ \sigma_\perp(v) = \perp$

The State Transformation Function

The state transformation function

$$\theta_\iota : \Sigma \to \Sigma, \quad \iota \equiv x := t$$

is defined by:

$$\forall\, \sigma \in \Sigma\ \forall\, y \in \mathbf{V}.\ \theta_\iota(\sigma)(y) =_{df} \begin{cases} \mathcal{E}(t)(\sigma) & \text{falls } y = x \\ \sigma(y) & \text{sonst} \end{cases}$$

Main Results

Lemma (5.4.2.1)

$[\![\ ]\!]_{sc}$ *is monotonic.*

Note: Distributivity does not hold! (Excercise)

Corollary (5.4.2.2)

The MOP solution and the MaxFP solution do in general not coincide. The MaxFP solution, however, is always a safe approximation of the MOP solution for simple constants.

Summing up

The previous examples demonstrate that in general we can not achieve

- computational, lifetime, and space optimality

at the same time.

Think, however, about the following problem (homework):

- Let P be a program containing partially redundant computations.

  Can you imagine an algorithm that always suceeds to transform P into a program P' such that P and P' have the same semantics and that P' is free of any partially redundant computation?

The Groundbreaking Algorithm for PRE

PRE is intrinsically tied to Etienne Morel und Claude Renvoise. The PRE algorithm they presented in 1979 can be considered the *prime father* of all code motion (CM) algorithms and was until the early 1990s the "state of the art" PRE algorithm.

Technically, the PRE algorithm of Morel and Renvoise is composed of:

- 3 uni-directional bitvector analyses (AV, ANT, PAV)
- 1 bi-directional bitvector analysis (PP)

Chap. 17

Summing up (2)

Short-comings of Morel&Renvoise's PRE algorithm:

- Conceptually
  - Fails computational optimality
    $\rightsquigarrow$ only, however, because of not splitting critical edges
  - Fails lifetime optimality
    $\rightsquigarrow$ Register pressure is heuristically dealt with
  - Fails code-size optimality
    $\rightsquigarrow$ Not considered at all (in the early days of PRE)
- Technically
  - Bi-directional
    $\rightsquigarrow$ conceptually and computationally thus more complex

...the transformation result lies (unpredictably) between those of the BCM transformation and the LCM transformation.

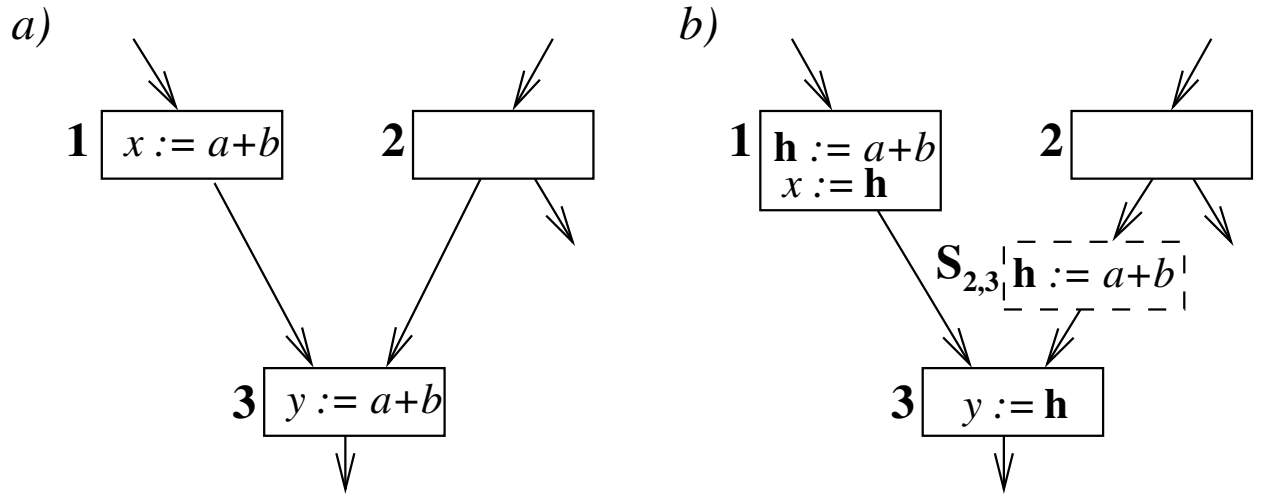
Critical Edges

An edge is called critical, if it connects a branching node with a join node.

Illustration:



...by introducing the synthetic node $\mathbf{S}_{2,3}$, the critical edge from node **2** to node **3** is split which allows to eliminate the partially redundant computation of $a + b$ at node **3**.

Notations

Given a flow gragh $G = (N, E, \mathbf{s}, \mathbf{e})$ let

- $pred(n) =_{df} \{m \mid (m, n) \in E\}$ denote the set of all predecessors
- $succ(n) =_{df} \{m \mid (n, m) \in E\}$ denote the set of all successors
- $source(e)$, $dest(e)$ denote the start node and end node of an edge
- a sequence of edges $(e_1, \ldots, e_k)$ with $dest(e_i) = source(e_{i+1})$ for all $1 \leq i < k$ denote a finite path.

  Note: Instead of edge sequences we also consider node sequences as paths, where reasonable.

Notations (Cont'd)

More specifically:

- $p = \langle e_1, \ldots, e_k \rangle$ denotes a path from m to n, if $source(e_1) = m$ and $dest(e_k) = n$
- $\mathbf{P}[m, n]$ denotes the set of all paths from m to n
- λ_p denotes the length of p, i.e., the number of edges of p
- ε denotes the path of length 0
- $N_J \subseteq N$ denotes the set of join nodes, i.e., the set of nodes w/ more than one predecessor
- $N_B \subseteq N$ denotes the set of branch nodes, i.e. the set of nodes w/ more than one successor

Convention

W/out losing generality we assume:

- Each node of a flow graph lies on a path from **s** to **e**

  Intuition: There are no unreachable parts within a flow graph.

...this is a typical and usual assumption for analysis and optimization!

Contents

An additional CM specific Convention

W/out losing generality we focus in the following on flow graphs given

- as node labelled SI graphs
- where all edges leading to a join node are split by inserting a so-called synthetic node (i.e., not just critical edges are split)

Contents

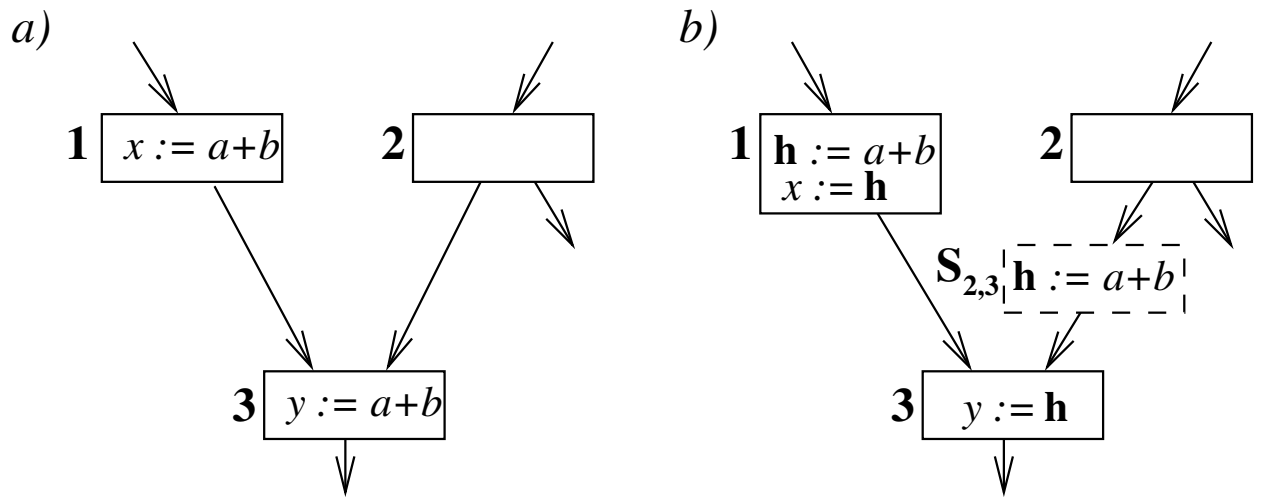
Reminder: Critical Edges

An edge is called critical, if it connects a branching node with a join node.

Illustration: ...by introducing the synthetic node $\mathbf{S}_{2,3}$, the critical edge from node **2** to node **3** is split.



In the following we assume that also edges like the one from node **1** to node **3** are split by introducing a new node $\mathbf{S}_{1,3}$.

Chap. 12
Chap. 13
Chap. 14
Chap. 15
Chap. 16
Chap. 17

Background and Motivation

...underlying this convention:

- The CM process becomes simpler.

  $\rightsquigarrow$ computationally optimal results can be achieved by initializing temporaries always at node entries.

Contents
Chap. 1
Chap. 2
Chap. 3
Chap. 4

Chap. 12
Chap. 13
Chap. 14
Chap. 15
Chap. 16
Chap. 17

Note

Computationally optimal results can also be achieved, if only critical edges are split.

This, however, requires that a PRE algorithm is able to perform initializations both at node entries (N-initializations) and at node exits (X-Initializations).

This is not a problem at all. Agreeing, however, on the above assumption simplifies the presentation of the CM algorithm even more.

The Generic Pattern of a CM Transformations

The generic 3-step (transformation) pattern for a term t:

- Introduce a fresh temporary h for t in G
- Insert at some nodes of G the assignment statement $h := t$
- Replace some of the original occurrences of t in G by h

Remark: t is often called a candidate expression.

Chap. 16
Chap. 17

Observation

Two predicates (defined on nodes)

- $Insert_{CM}$
- $Repl_{CM}$

suffice to specify a CM (resp. PRE) transformation completely

(the first step of declaring the temporary h is the same for each CM transformation and thus does not need to be considered explicitly).

Chap. 13
Chap. 14
Chap. 15
Chap. 16
Chap. 17

Observation

Obviously, some transformations in $\mathcal{CM}$ do not preserve the semantics and are thus not acceptable.

This leads us to the notion of admissible CM transformations.

Chap. 17

Admissible CM Transformations

Let $CM \in \mathcal{CM}$.

CM is called admissible, if CM is safe and correct.

Intuitively:

- Safe: There is no path, on which by inserting an initialization a new value is computed.
- Correct: Whereever the temporary is used, it stores the "right" value, i.e., it stores the same value that a recomputation of t at the use site yields.

Chap. 16
Chap. 17

Formalising this

...requires two (local) predicates:

- $Comp_t(n)$: the candidate expression t is computed at n.
- $Transp_t(n)$: n is transparent for t, i.e., n does not modify any operand of t.

Note: In the following we will drop the index t.

Moreover, it is useful to introduce a third (local) predicate:

- $Comp_{CM}(n) =_{df} Insert_{CM}(n) \vee Comp(n) \wedge \neg Repl_{CM}(n)$: The candidate expression t is computed after the application of CM.

Extending Predicates from Nodes to Paths

Let p be a path and let p_i denote the ith node of p.

Then we define:

- $Predicate^{\forall}(p) \iff \forall 1 \leq i \leq \lambda_p.\ Predicate(p_i)$
- $Predicate^{\exists}(p) \iff \exists 1 \leq i \leq \lambda_p.\ Predicate(p_i)$

Safety and Correctness

Definition (7.1.1, Safety and Correctness)

Let $n \in N$. Then:

1. $Safe(n) \iff_{df}$
   $\forall \langle n_1, \ldots, n_k \rangle \in \mathbf{P}[s, e]\ \forall i.\ (n_i = n) \Rightarrow$
   $i)\ \exists j < i.\ Comp(n_j) \wedge Transp^{\forall}(\langle n_j, \ldots, n_{i-1} \rangle)\ \vee$
   $ii)\ \exists j \geq i.\ Comp(n_j) \wedge Transp^{\forall}(\langle n_i, \ldots, n_{j-1} \rangle)$
2. Let $CM \in \mathcal{CM}$. Then:
   $Correct_{CM}(n) \iff_{df} \forall \langle n_1, \ldots, n_k \rangle \in \mathbf{P}[s, n]$
   $\exists i.\ Insert_{CM}(n_i) \wedge Transp^{\forall}(\langle n_i, \ldots, n_{k-1} \rangle)$

Intuition

A computation of t at program point n is

- up-safe, if t is computed on all paths p from **s** to n and the last computation of t on p is not followed by a modification of (an operand of) t.
- down-safe, if t is computed on all paths p from n to **e** and the first computation of t on p is not preceded by a modification of (an operand of) t.

Admissible CM-Transformations

This allows us to define:

Definition (7.1.3, Admissible CM-Transformation)

A CM-transformation $CM \in \mathcal{CM}$ is admissible iff for every node $n \in N$ holds:

1. $Insert_{CM}(n) \Rightarrow Safe(n)$
2. $Repl_{CM}(n) \Rightarrow Correct_{CM}(n)$

The set of all admissible CM-transformations is denoted by $\mathcal{CM}_{Adm}$.

Computationally Better

Definition (7.1.6, Computationally Better)

A CM-transformation $CM \in \mathcal{CM}_{Adm}$ is computationally better as a CM-transformation $CM' \in \mathcal{CM}_{Adm}$ iff

$$\forall\ p \in \mathbf{P}[s, e].\ |\ \{i \mid Comp_{CM}(p_i)\}\ | \leq |\ \{i \mid Comp_{CM'}(p_i)\}\ |$$

Note: The relation "computationally better" is a quasi-order, i.e., a reflexive and transitive relation.

Computational Optimality

Definition (7.1.7, Comp. Optimal CM-Transf.)

An admissible CM-transformation $CM \in \mathcal{CM}_{Adm}$ is computa- tionally optimal iff CM is computationally better than any other admissible CM-transformation.

We denote the set of all computationally optimal CM-transformations by $\mathcal{CM}_{CmpOpt}$.

Properties of Relations – A Reminder

Let M be a set and R be a relation on M, i.e.,$R \subseteq M \times M$.

Then R is called

- reflexive iff $\forall\, m \in M.\ m\, R\, m$
- transitive iff $\forall\, m, n, p \in M.\ m\, R\, n \ \wedge\ n\, R\, p \ \Rightarrow\ m\, R\, p$
- anti-symmetric iff
  $\forall\, m, n \in M.\ m\, R\, n \ \wedge\ n\, R\, m \ \Rightarrow\ m = n$
- quasi order iff R is reflexive and transitive
- partial order iff R is reflexive, transitive and anti-symmetric

Almost Lifetime Optimal

Definition (8.2.5, Almost Lifetime Optimal CM-Transformation)

A computationally optimal CM-transformation $CM \in \mathcal{CM}_{CmpOpt}$ is almost lifetime optimal iff

$$\forall\, p \in LtRg(CM).\ \lambda_p \geq 2 \Rightarrow$$
$$\forall\, CM' \in \mathcal{CM}_{CmpOpt}\ \exists\, q \in LtRg(CM').\ p \sqsubseteq q$$

We denote the set of all almost lifetime optimal CM-transformations by $\mathcal{CM}_{ALtOpt}$.

Implementing Busy and Lazy Code Motion

...for node-labelled BB-graphs:

- BCM_β Transformation
- LCM_β Transformation

Convention: For the following we assume that (1) only critical edges are split. Therefore, BCM_β and LCM_β require insertions at both node entries and node exits (N-insertions and X-in- sertions), and that (2) all redundancies within a basic block have been removed by a preprocess.

Entry and Exit Parts of a Basic Block

For PRE, we do not need to distinguish between entry and middle part(s), and can consider them a unit. This gives rise to the following definition:

Given a computation t, a basic block **n** can be divided into two parts:

- an entry part which consists of all statements up to and including the last modification of t
- an exit part which consists of the remaining statements of **n**.

Note: The entry part of a non-empty basic block is always non-empty; in distinction, the exit part of a non-empty basic block can be empty itself (this is illustrated in the following figure).

The General Pattern of CM on BB-Graphs

1. Introducing temporay
   1.1 Define a new temporary variable $\mathbf{h}_{CM}$ for t.
2. Insertions
   2.1 Insert assignments $\mathbf{h}_{CM} := t$ at the insertion point of the entry art of all $\beta \in \mathbf{N}$ satisfying N-INSERT^{CM}
   2.2 Insert assignments $\mathbf{h}_{CM} := t$ at the insertion point of the exit part of all $\beta \in \mathbf{N}$ satisfying X-INSERT^{CM}
3. Replacements
   3.1 Replace the (unique) entry computation of t by $\mathbf{h}_{CM}$ in every $\beta \in \mathbf{N}$ satisfying N-REPLACE^{CM}
   3.2 Replace the (unique) exit computation of t by $\mathbf{h}_{CM}$ in every $\beta \in \mathbf{N}$ satisfying X-REPLACE^{CM}

Local Predicates for BCM_β and LCM_β

Local Predicates:

- BB-NCOMP$_\beta(t)$: β contains a statement ι that computes t, and that is not preceded by a statement that modifies an operand of t.
- BB-XCOMP$_\beta(t)$: β contains a statement ι that computes t and neither ι nor any other statement of β after ι modifies an operand of t.
- BB-TRANSP$_\beta(t)$: β contains no statement that modifies an operand of t.

Code for Embedded Systems

Demands:

- Performance (often real-time demands)
- Code size (system-on-chip, on-chip RAM/ROM)
- ...

For embedded systems:

- Code size is often more critical than speed!

Code for Embedded Systems (Cont'd)

Demands (and how they are often still addressed):

- Assembler programming
- Manual post-optimization

Shortcomings:

- Error prone
- Delayed time-to-market

...problems getting more severe with increasing complexity.

Generally, we observe:

- a trend towards high-level languages programming (C/C++)

Code-size Sensitive PRE

- ⇝ The Problem
  ...how do we get code-size minimal placement of the computations, i.e., a placement that is
  - admissible (semantics & performance preserving)
  - code-size minimal?
- ⇝ The Solution: A new View to PRE
  ...consider PRE as a trade-off problem: Exchange original computations for newly inserted ones!
- ⇝ The Clou: Use Graph Theory!
  ...reduce the trade-off problem to the computation of tight sets in bipartite graphs based on maximum matchings!

We postpone but keep in mind

...that we have to answer:

- Where are computations to be inserted and where are original computations to be replaced?

...and to prove:

- Why is this correct (i.e., semantics preserving)?
- What is the impact on the code size?
- Why is this "optimal" wrt a given prioritization of goals?

For each of these questions we will provide a specific theorem that yields the corresponding answer!

Chap. 17

Main Results / Question 1

1. Where to insert computations, why is it correct?

Intuitively: At the earliestness frontier of the DS-region induced by the tight set.

Theorem (10.6, Tight Sets: Insertion Points)

Let $TS \subseteq S_{DS}$ *be a tight set.*
Then $\mathcal{R}_{TS} =_{df} \Gamma(TS) \cup (Comp \setminus UpSafe)$
is a down-safety region w/ $Body_{\mathcal{R}_{TS}} = TS$

Correctness

- An immediate corollary of Theorem 10.6 and the Initialization Theorem 10.5

Chap. 15
Chap. 16
Chap. 17

Main Results / Question 2

2. What is the impact on the code size?

Intuitively: The difference between the number of inserted and replaced computations.

Theorem (10.7, Down-Safety Regions: Space Gain)

Let $\mathcal{R}$ be a down-safety region w/ $Body_{\mathcal{R}} =_{df} \mathcal{R} \setminus EarliestFrontier_{\mathcal{R}}$

Then

- *Space Gain by Inserting at $EarliestFrontier_{\mathcal{R}}$:* $|Comp \setminus UpSafe| - |EarliestFrontier_{\mathcal{R}}| = |Body_{\mathcal{R}}| - |\Gamma(Body_{\mathcal{R}})| \quad_{df} = defic(Body_{\mathcal{R}})$

Main Results / Question 3

3. Why is the result optimal, i.e., code-size minimal?

Intuitively: Due to a property inherent to tight sets (non-negative deficiency!).

Theorem (10.8, Optimality: Transformation)

Let $TS \subseteq S_{DS}$ be a tight set.

- *Insertion Points:*
  $Insert_{SpCM} =_{df} EarliestFrontier_{\mathcal{R}_{TS}} = \mathcal{R}_{TS} \setminus TS$
- *Space Gain:*
  $defic(TS) =_{df} |TS| - |\Gamma(TS)| \geq 0$ *max.*

Code-size Sensitive PRE at a Glance

Preprocess

- **Optional:** Perform LCM (3 GEN/KILL–DFAs)
- Compute Predicates of LCM for G resp. LCM(G) (2 GEN/KILL–DFAs)

Main Process

Reduction Phase

- Construct Bipartite Graph
- Compute Maximum Matching

Optimization Phase

- Compute Largest/Smallest Tight Set
- Determine Insertion Points

Objective

Developing a program optimization that

- uniformly covers
  - Partial Redundancy Elimination (PRE) and
  - Strength Reduction (SR)
- avoids superfluous register pressure due to unnecessary code motion
- requires only uni-directional data flow analyses

The Approach:

- Stepwise and modularly extending the *BCM* and the *LCM* to arrive at the
  - Busy (*BSR*) and Lazy Strength Reduction (*LSR*)

From PRE towards LSR (1)

First, the notion of a candidate expression has to be adapted:

Candidate expressions for

- PRE: Each term t
- SR: Terms of the form $v * c$, where
  - v is a variable
  - c is a source code constant

Contents

Chap. 12
Chap. 13
Chap. 14
Chap. 15
Chap. 16
Chap. 17
Chap. 18

From PRE towards LSR (2)

Second, the set of local predicates has to be extended:

- $Used(n) =_{df} v * c \in SubTerms(t)$
- $Transp(n) =_{df} x \not\equiv v$
- $SR\text{-}Transp(n) =_{df} Transp(n) \vee t \equiv v + d$ with $d \in \mathbf{C}$

Intuitively

The value of a candidate expression is

- killed at a node n, if $\neg(Transp(n) \vee SR\text{-}Transp(n))$
- injured at a node n, if $\neg Transp(n) \wedge SR\text{-}Transp(n)$

Important: Injured but not killed values can be

- cured by inserting an update assignment of the form $\mathbf{h} := \mathbf{h} + Eff(n)$ where $Eff(n) =_{df} c * d$.

  Note that $Eff(n)$ can be computed at compile time since both c and d are source code constants.

Extending BCM straigthforward to SR

...leads to Simple Strength Reduction (*SSR*).

The *SSR*-Transformation:

1. Introduce a new auxiliary variable $\mathbf{h}$ for $v * c$
2. Insert at the entry of every node satisfying
   2.1 $\mathtt{Ins}_{\mathtt{SSR}}$ the assignment $\mathbf{h} := v * c$
   2.2 $\mathtt{InsUpd}_{\mathtt{SSR}}$ the assignment $\mathbf{h} := \mathbf{h} + \mathit{Eff}(n)$
3. Replace every (original) occurrence of $v * c$ in G by $\mathbf{h}$

Note: If both $\mathtt{Ins}_{\mathtt{SSR}}$ and $\mathtt{InsUpd}_{\mathtt{SSR}}$ hold, the initialization statement $\mathbf{h} := v * c$ must precede the update assignment $\mathbf{h} := \mathbf{h} + \mathit{Eff}(n)$.

Discussing the Effect of *SSR*

Shortcoming

- The multiplication-addition-deficiency

Remedy:

- Moving critical insertion points in the direction of the control flow to "earliest" non-critical ones.

Intuitively:

- A program point is critical if there is a $v * c$-free program path from this point to a modification of v

The 1st Refinement of *SSR*

The SSR_{FstRef}-Transformation:

1. Introduce a new auxiliary variable $\mathbf{h}$ for $v * c$
2. Insert at the entry of every node satisfying
   2.1 $\mathtt{Ins}_{FstRef}$ the assignment $\mathbf{h} := v * c$
   2.2 $\mathtt{InsUpd}_{FstRef}$ the assignment $\mathbf{h} := \mathbf{h} + Eff(n)$
3. Replace every (original) occurrence of $v * c$ in G by $\mathbf{h}$

Homework

Assignment 5:

1. Specify the data flow analyses and transformations for
   - SSR
   - SSR_{FstRef} (overcoming the multiplication-addition deficiency)
   - SSR_{SndRef} (overcoming the register-pressure deficiency)
   - $SSR_{ThdRef} = LSR$ (overcoming the multiple-addition deficiency)
2. implement them in PAG, and
3. validate them on the running example of this chapter (or an example coming close to it).

Motivation

Why is it rewarding to consider PRE?

Because PRE is

- General: A family of optimizations rather than a single optimization
- Well understood: Proven correct and optimal
- Relevant: Widely used in practice because of its power
- Truly classical: Looks back to a long history beginning with
  - Etienne Morel, Claude Renvoise. Global Optimization by Suppression of Partial Redundancies. Communications of the ACM 22(2):96-103, 1979.
  - Andrei P. Ershov. On Programming of Arithmetic Operations. Communications of the ACM 1(8):3-6, 1958.

Chap. 15

Motivation (Cont'd)

Last but not least, PRE is

- Challenging: Conceptually simple but exhibits a variety of thought provoking phenomenons

Some of these challenges we are going to sketch next.

Code Motion Reconsidered

Traditionally:

- Code (C) means expressions
- Motion (M) means hoisting

But:

- CM is more than hoisting of expressions and PR(E)E!

Design Space of CM-Algorithms (1)

This results in the following design space of CM-algorithms:

Generally:

- Code means expressions/assignments
- Motion means hoisting/sinking

Code / Motion	Hoisting	Sinking
Expressions	EH	·/·
Assignments	AH	AS

What is the Impact on Optimality?

Optimality statements are quite sensitive towards setting changes!

Three examples shall provide evidence for this:

- Code motion vs. code placement
- Interdependencies of elementary transformations
- Paradigm dependencies

Optimality Results for (Pure) PRAE/PDCE

Deriving relation $\vdash$...

- PRAE... $G \vdash_{AH,TRAE} G'$ (ET={AH,TRAE})
- PDCE... $G \vdash_{AS,TDCE} G'$ (ET={AS,TDCE})

We can prove:

Theorem (12.2.2, Optimality)

For PRAE and PDCE the deriving relation $\vdash_{ET}$ is confluent and terminiating.

Chap. 14
Chap. 15

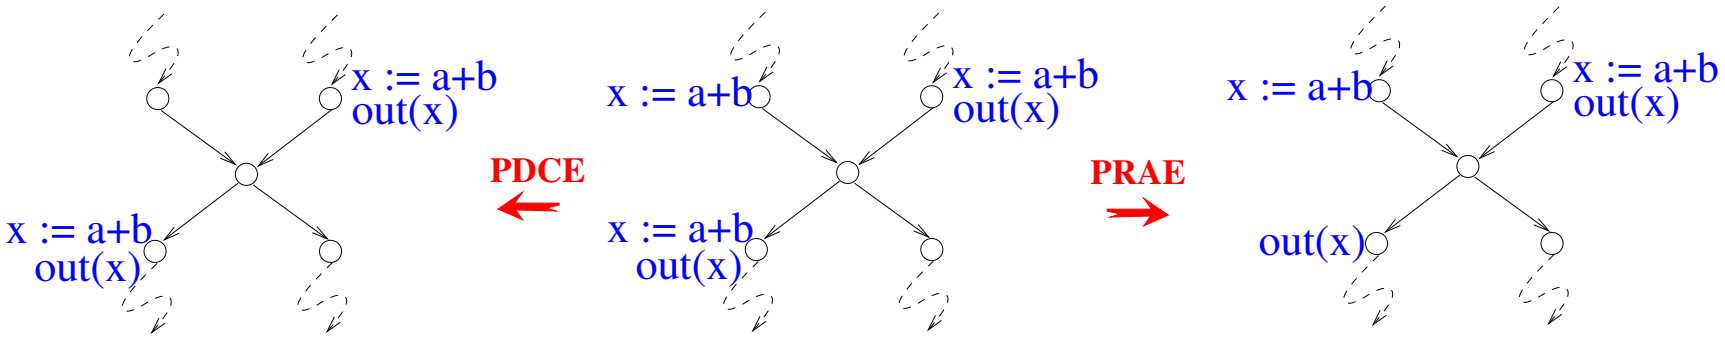
Now

...extend and amalgate PRAE and PDCE to Assignment Placement (AP):

- AP = (AH + TRAE + AS + TDCE)*

...AP should be more powerful than PRAE and PDCE alone!

Indeed, it is but:



The resulting two programs are incomparable.

Outline

From intraprocedural to interprocedural data-flow analysis...

To this end we extend our programming language WHILE by introducing programs with

- top-level declarations of global mutually recursive procedures and
- a call-by-value and a call-by-result parameter.

Note: Extensions to multiple call-by-value, call-by-result, and call-by-value-result parameters are straightforward.

Syntax

Extended WHILE-Language WHILE$_\pi$:

$$
\begin{array}{lcl}
P_\star & ::= & \text{begin } D_\star \; S_\star \text{ end} \\
D & ::= & D; D \;\mid\; \text{proc } p(\text{val } x;\ \text{res } y) \text{ is}^{\ell_n} \; S \text{ end}^{\ell_x} \\
S & ::= & \ldots \;\mid\; [\text{call } p(a, z)]_{\ell_r}^{\ell_c}
\end{array}
$$

Labeling scheme

- Procedure declarations

  ℓ_n: for entering the body

  ℓ_x: for exiting the body

- Procedure calls

  ℓ_c: for the call

  ℓ_r: for the return

Chap. 18

Assumptions

We assume that

- WHILE_π is statically scoped.
- The parameter mechanism is
  - call-by-value for the first parameter
  - call-by-result for the second parameter.
- Procedures may be mutually recursive.
- Programs are uniquely labelled.
- There are no procedures of the same name.
- Only procedures may be called by a program that have been declared in it.

Example

The procedure `proc fib` computing the Fibonacci numbers:

```
begin
   proc fib(val z,u; res v) is
      if z<3 then
         (v:=u+1; r:=r+1)
      else (
         call fib (z-1,u,v);
         call fib (z-2,v,v)
         )
   end;
r:=0;
call fib(x,0,y)
end
```

Notions and Notations for Flow Graphs (1)

...for procedure calls and procedure declarations:

	$[\text{call } p(a,z)]^{\ell_c}_{\ell_r}$	$\text{proc } p(\text{val } x;\ \text{res } y)\ \text{is}^{\ell_n}\ S\ \text{end}^{\ell_x}$
init	ℓ_c	ℓ_n
final	$\{\ell_r\}$	$\{\ell_x\}$
blocks	$\{[\text{call } p(a,z)]^{\ell_c}_{\ell_r}\}$	$\{\text{is}^{\ell_n}\} \cup \text{blocks}(S) \cup \{\text{end}^{\ell_x}\}$
labels	$\{\ell_c, \ell_r\}$	$\{\ell_n, \ell_x\} \cup \text{labels}(S)$
flow	$\{(\ell_c; \ell_n), (\ell_x; \ell_r)\}$	$\{(\ell_n, \text{init}(S))\} \cup \text{flow}(S) \cup \{\ell, \ell_x) \mid \ell \in \text{final}(S))\}$

Note: $(\ell_c; \ell_n)$ and $(\ell_x; \ell_r)$ denote a new kind of flow, interprocedural flow:

- $(\ell_c; \ell_n)$ is the flow corresponding to calling a procedure at ℓ_c and entering the procedure body at ℓ_n and
- $(\ell_x; \ell_r)$ is the flow corresponding to exiting a procedure body at ℓ_x and returning to the call at ℓ_r.

Remark: Intraprocedural flow uses ',' while interprocedural flow uses ';'.

Towards Interprocedural DFA

New transfer functions dealing with interprocedural flow are required:

- For each procedure call $[\text{call } p(a, z)]^{\ell_c}_{\ell_r}$ we require two transfer functions
  - f_{l_c} and f_{l_r}

  corresponding to calling the procedure and returning from the call.
- For each procedure definition proc $p(\text{val } x;\ \text{res } y)$ is$^{\ell_n}$ S end$^{\ell_x}$ we require two transfer funcions
  - f_{l_n} and f_{l_x}

  corresponding to entering and exiting the procedure body.

Interprocedural DFA: Naive Formulation (1)

- Treat the three kinds of flow, (ℓ_1, ℓ_2), $(\ell_c; \ell_n)$, $(\ell_x; \ell_r)$ in the same way.
- Assume that the 4 transfer functions associated with procedure calls and procedure definitions are given by the identity functions, i.e., the parameter-passing is effectively ignored.

Then:

Naive Interprocedural *MaxFP*-Equation System:

$$\begin{array}{lcl} A_\circ(\ell) & = & \bigsqcap\{A_\bullet(\ell') \mid (\ell', \ell) \in F \vee (\ell'; \ell) \in F\} \sqcap \iota_E^\ell \\ A_\bullet(\ell) & = & f_\ell^A(A_\circ(\ell)) \end{array}$$

where

$$\iota_E^\ell =_{df} \begin{cases} \iota & \text{if } I \in E \\ \bot & \text{if } I \notin E \end{cases}$$

Chap. 18

Interprocedural DFA: Naive Formulation (2)

Given the previous assumptions we have:

- Both procedure calls $(\ell_c; \ell_n)$ and procedure returns $(\ell_x; \ell_r)$ are treated like "goto's".
- There is no mechanism for ensuring that information flowing along $(\ell_c; \ell_n)$ flows back along $(\ell_x; \ell_r)$ to the *same* call
- Intuitively, the equation system considers a much too large set of "paths" through the program and hence will be grossly imprecise (although formally on the safe side)

Interprocedural DFA: Naive Formulation (3)

We want to overcome the shortcoming of the naive formulation by restricting attention to paths that have the proper nesting of procedure calls and exits. Important are the notions of matching procedure entries and exits and of complete and valid paths.

Chap. 16
Chap. 17

Complete Paths

A complete path from ℓ_1 to ℓ_2 in $P_\star$ has proper nesting of procedure entries and exits; and a procedure returns to the point where it was called:

$$
\begin{array}{ll}
CP_{\ell_1,\ell_2} \longrightarrow \ell_1 & \text{whenever } \ell_1 = \ell_2 \\
CP_{\ell_1,\ell_3} \longrightarrow \ell_1, CP_{\ell_2,\ell_3} & \text{whenever } (\ell_1, \ell_2) \in \text{flow}_\star \\
CP_{\ell_c,\ell} \longrightarrow \ell_c, CP_{\ell_n,\ell_x}, CP_{\ell_r,\ell} & \text{whenever } (\ell_c, \ell_n, \ell_x, \ell_r) \in \text{inter-flow}_\star
\end{array}
$$

Recall:
$(\ell_c, \ell_n, \ell_r, \ell_x) \in \text{inter-flow}_\star$, if $P_\star$ contains $[\text{call } p(a, z)]_{\ell_r}^{\ell_c}$ as well as $\text{proc } p(\text{val } x;\ \text{res } y) \text{ is}^{\ell_n}\ S \text{ end}^{\ell_x}$.

Chap. 17

Valid Paths

A valid path starts at the entry node $\mathsf{init}_\star$ of $P_\star$, all the procedure exits match the procedure entries but some procedures might be entered but not yet exited:

$$
\begin{array}{ll}
VP_\star \longrightarrow VP_{\mathsf{init}_\star,\ell} & \text{whenever } \ell \in \mathsf{Lab}_\star \\
VP_{\ell_1,\ell_2} \longrightarrow \ell_1 & \text{whenever } \ell_1 = \ell_2 \\
VP_{\ell_1,\ell_3} \longrightarrow \ell_1,\, VP_{\ell_2,\ell_3} & \text{whenever } (\ell_1,\ell_2) \in \mathsf{flow}_\star \\
VP_{\ell_c,\ell} \longrightarrow \ell_c,\, CP_{\ell_n,\ell_x},\, VP_{\ell_r,\ell} & \text{whenever } (\ell_c,\ell_n,\ell_x,\ell_r) \in \text{inter-flow}_\star \\
VP_{\ell_c,\ell} \longrightarrow \ell_c,\, VP_{\ell_n,\ell} & \text{whenever } (\ell_c,\ell_n,\ell_x,\ell_r) \in \text{inter-flow}_\star
\end{array}
$$

Note: The valid paths are generated by the non-terminal $VP_\star$.

Discussing the MVP Solution (1)

The MVP solution may be undecidable (even) for lattices satisfying the Descending Chain Condition, just as was the case for the MOP solution.

Therefore, we need to reconsider the maximal fixed point approach and adapt it to

- avoid considering too many paths
- taking call context information into account.

Chap. 15
Chap. 16
Chap. 17

Discussing the MVP Solution (2)

In more detail:

We have to

- reconsider the MFP solution and avoid taking too many invalid paths into account.

An obvious approach is to

- encode information about the paths taken into the data flow properties themselves.

This can be achieved by

- introducing context information $\delta \in \Delta$.

Towards the MFP Counterpart

- Context insensitive analysis: No context information is used.
- Context sensitive analysis: Context information $\delta \in \Delta$ is used.
  - Call strings:
    - An abstraction of the sequences of procedure calls that have been performed so far.
    - Example: The program point where the call was initiated.
  - Assumption sets:
    - An abstraction of the states in which previous calls have been performed.
    - Example: An abstraction of the actual parameters of the call.

Call Strings δ as Context Information Δ

- Encode the path taken.
- Only record flows of the form $(\ell_c; \ell_n)$ corresponding to a procedure call.
- we take as context $\Delta = \mathrm{Lab}_*^*$ where the most recent label ℓ_c of a procedure call is at the right end.
- Elements of Δ are called call strings.
- The sequence of labels $\ell_c^1, \ell_c^2, \ldots, \ell_c^m$ is the call string leading to the current call which happened at ℓ_c^m; the previous calls where at $\ell_c^2 \ldots \ell_c^1$. If $m = 0$ then no calls have been performed so far.

For the example program the following call strings are of interest:

$$\Lambda, [11], [11, 5], [11, 7], [11, 5, 5], [11, 5, 7], [11, 7, 5], [11, 7, 7], \ldots$$

The Adapted MFP Equation System

The Adapted MFP-Equation System:

$$\begin{aligned} A_\circ(\ell) &= \bigsqcap\{A_\bullet(\ell') \mid (\ell',\ell) \in F \vee (\ell';\ell) \in F\} \sqcap \widehat{\iota_E^\ell} \\ A_\bullet(\ell) &= \widehat{f_\ell^A}(A_\circ(\ell)) \end{aligned}$$

where

- $\hat{L} = \Delta \to L$ maps a context to a data flow property (i.e., a data flow lattice element)
- each transfer function $\widehat{f_l}$ is given by $\widehat{f_l}(\hat{l})(\delta) = f_l(\hat{l}(\delta))$ (i.e., $\widehat{f_l}$ adapts resp. specializes f_l to the call context δ)
- $$\widehat{\iota_E^\ell} =_{df} \begin{cases} \iota_E^\ell & \text{if } \delta = \Lambda \\ \bot & \text{otherwise} \end{cases}$$

Making it Practical: Bounding Call Strings

Problem: Call strings can be arbitrarily long (recursive calls)

Solution: Truncate the call strings to have length of at most k for some fixed number k

In practice:

- $\triangle = \mathrm{Lab}_*^{\leq k}$, i.e. call strings of bounded length k.
- $k = 0$: Context insensitive analysis
  - Λ (the call string is the empty string)
- $k = 1$: Remember the last procedure call
  - $\Lambda, [11], [5], [7]$
- $k = 2$: Remember the last two procedure calls
  - $\Lambda, [11], [11, 5], [11, 7], [5, 5], [5, 7], [7, 5], [7, 7]$
- ...

Assumption Sets δ as Context Information Δ

Instead of describing a path directly in terms of teh calls being performed (as a textcolorbluecall string does), information about the state in which a call was made can be stored (as an textcolorblueassumption set does).

For a more detailed account of the textcolorblueassumption set approach refer to

Function Pointers

Values of function pointer variables

The value of a function pointer variable is the address of a function. At run-time different values can be assigned to pointer variables.

Interprocedural Control Flow

Any function with the same signature (=parameter types) can be potentially called by using a function pointer.

Program analysis can reduce the number of functions that may be called at run-time by computing the set of possible pointer values assigned to function pointer variables in a given program.

Virtual Function Calls & Overloaded Functions

...in object-oriented programming.

Virtual function calls

By taking the class hierarchy into account, we can limit the methods that can be called to the set of overriding methods of subclasses. Program analysis can further reduce the number of methods that may be called at run-time.

Overloaded functions

Calls to overloaded functions are resolved at compile time.

Flow Graph Systems

Definition (14.1.1, Flow Graph System)

A flow graph system $S =_{df} \langle G_0, \ldots, G_k \rangle$ is a system of (intra-procedural) flow graphs in the sense of Chapter 4, where each flow graph G_i represents a procedure of the underlying program Π. The flow graph G_0 of S represents the main procedure or the main program of Π.

Interprocedural Flow Graphs

Definition (14.1.2, Interprocedural Flow Graph)

A flow graph system S induces an interprocedural flow graph, where the flow graphs of S are melted to a single flow graph $G^* = (N^*, E^*, \mathbf{s}^*, \mathbf{e}^*)$.

G^* evolves from S by replacing each call edge e of a procedure π by two new edges e_c and e_r.

The edge e_c connects the source node of e w/ the start node of the called procedure.

The edge e_r connects the end node of the called procedure w/ the final node of e.

Notations for Flow Graph Systems

- G_0 represents the main procedure.
- The start node $\mathbf{s}_0$ of G_0 is often abbreviated by $\mathbf{s}$.
- The sets of nodes and edges N_i und E_i, $0 \leq i \leq k$, are assumed to be pairwise disjoint.
- $N =_{df} \bigcup\{N_i \mid i \in \{0, \ldots, k\}\}$ and $E =_{df} \bigcup\{E_i \mid i \in \{0, \ldots, k\}\}$ denote the set of all nodes and edges of a flow graph system.
- $E_{call} \subseteq E$ denotes the set of edges, which represent a procedure call, for short, the set of call edges.

The Key to Interprocedural DFA (1)

The Functional *MaxFP*-Approach:

The "functional" *MaxFP* results from lifting the analysis level from elements to functions. It is the pointwise extension of the *MaxFP* approach to all DFA-lattice elements:

The Functional *MaxFP* Equation System 14.1.3

$$[\![n]\!] = \begin{cases} Id_{\mathcal{C}} & \text{if } n = \mathbf{s} \\ \bigsqcap \{ [\![(n, m)]\!] \circ [\![m]\!] \mid m \in pred(n) \} & \text{otherwise} \end{cases}$$

Let

$$[\![\;\;]\!]^* : N \to (\mathcal{C} \to \mathcal{C})$$

denote the greatest solution of the above equation system.

The Key to Interprocedural DFA (2)

Intuitively

The functional *MaxFP* approach lifts the *MaxFP* approach to the level of functions, i.e.

- it computes the *MaxFP* solution not just for a specially selected single lattice element as start information but simultaneously for all.

The Key to Interprocedural DFA (3)

MaxFP approach vs. functional *MaxFP* approach:

The Equivalence Theorem 14.1.4 characterizes the relationship of the *MaxFP* approach and the functional *MaxFP* approach:

Theorem (14.1.4, Equivalence)

$\forall\, n \in N\ \forall\, c_{\mathsf{s}} \in \mathcal{C}.\ MaxFP_{(G,[\![\ ]\!])}(n)(c_s) = [\![\, n \,]\!]^*(c_{\mathsf{s}})$

In the following we will overload the symbol $[\![\ ]\!]$ and use it to also denote the greatest fixed point $[\![\, n \,]\!]^*$ of the functional *MaxFP* equation system 14.1.3.

Interprocedurally Valid Paths (1)

Observations:

- The notion of a finite path for intraprocedural flow graphs extends naturally to interprocedural flow graphs.
- Unlike, however, as in intraprocedural flow graphs, where each path connecting two nodes represents (up to non-determinism) a possible execution of the program, this does not hold for interprocedural flow graphs.
- In interprocedural DFA this is taken care of by focusing on interprocedurally valid paths.

Interprocedurally Valid Paths (2)

Intuitively: Interprocedurally valid paths respect the call/return behaviour of procedures.

Definition (14.1.2.1, Interprocedurally Valid Path)

Identifying call and return edges of G^* with opening and closing brackets "(" and ")", the set of interprocedurally valid paths is given by the set of prefix-closed expressions of the language of balanced bracket expressions.

Notation: In the following we denote the set of interprocedurally valid paths (for short: interprocedural paths) from a node m to a node n by $\mathbf{IP}[m, n]$.

Interprocedurally Valid Paths (3)

Observation: If we consider the sequences of edge labelings (we suppose that each edge is uniquely marked by some label) of a path as word of a formal language, then the set of intraprocedurally valid paths is given by a regular language, the one of interprocedurally valid paths by a context-free language.

Note:

- Sharir and Pnueli gave an algorithmic definition of interprocedurally valid paths in 1981.
- An immediate definition of interprocedurally valid paths in terms of a context-free language is possible, too.
- The definition of interprocedurally valid paths as in Definition 14.1.2.1 is due to Reps, Horwitz, and Sagiv, POPL'95.

Notations

The definition of the *IMaxFP* approach requires the following mappings on a flow graph system S:

- $\mathit{flowGraph} : N \cup E \to S$ maps the nodes and edges of S to the flow graph containing them.
- $\mathit{callee} : E_{call} \to S$ maps every call edge to the flow graph of the called procedure.
- $\mathit{caller} : S \to \mathcal{P}(E_{call})$ maps every flow graph to the set of call edges calling it.
- $\mathit{start} : S \to \{\mathbf{s}_0, \ldots, \mathbf{s}_k\}$ and $\mathit{end} : S \to \{\mathbf{e}_0, \ldots, \mathbf{e}_k\}$ map every flow graph of S to its start node and stop node.

The *IMaxFP* Approach (2)

Stage 2: Main Process – The "Actual" Interprocedural DFA

The 1st Order *IMaxFP* Equation System 14.1.3.2

$$inf(n) =$$

$$\begin{cases} c_{\mathbf{s}} & \text{if } n = \mathbf{s}_0 \\ \bigsqcap \{\, inf(src(e)) \mid e \in caller(flowGraph(n)) \,\} & \text{if } n \in \{\mathbf{s}_1, \ldots, \mathbf{s}_k\} \\ \bigsqcap \{\, [\![(m,n)]\!](inf(m)) \mid m \in pred_{flowGraph(n)}(n) \,\} & \text{otherwise} \end{cases}$$

The *IMaxFP* Solution:

$$\forall\, c_{\mathbf{s}} \in \mathcal{C}\ \forall\, n \in N.\ IMaxFP_{c_{\mathbf{s}}}(n) =_{df} inf^*_{c_{\mathbf{s}}}(n)$$

Main Results – 1st Stage

Safety and coincidence results of the 2nd-order 1st-stage analysis:

Theorem (14.1.4.1, 2nd Order)

For all $e \in E_{call}$ *hold:*

1. $[\![e]\!] \sqsubseteq \bigsqcap\{[\![p]\!]' \mid p \in \mathbf{CIP}[src(e), dst(e)]\}$, *if the data flow analysis functional* $[\![\ ]\!]'$ *is monotonic.*
2. $[\![e]\!] = \bigsqcap\{[\![p]\!]' \mid p \in \mathbf{CIP}[src(e), dst(e)]\}$, *if the data flow analysis functional* $[\![\ ]\!]'$ *is distributive.*

where the mappings *src* and *dst* yield the start and final node of an edge.

Complete Interprocedural Paths

Definition (14.1.4.2, Complete Interproc. Path)

An interprocedural path p from the start node $\mathbf{s}_i$ of a procedure G_i, $i \in \{0, \ldots, k\}$, to a node n within G_i is complete, if every procedure call, i.e., call edge, along p is completed by a corresponding procedure return, i.e., a return edge.

We denote the set of all complete interprocedural paths from $\mathbf{s}_i$ to n with $\mathbf{CIP}[\mathbf{s}_i, n]$.

Note:

- Intuitively, the completeness requirement states that the occurrences of $\mathbf{s}_i$ and n belong to the same incarnation of the procedure.
- We have that the subpaths of a complete interprocedural path that belong to a procedure call, are either disjoint or properly nested.

Main Results – 2nd Stage

Safety and coincidence results of the 1st-order 2nd-stage analysis:

Theorem (14.1.4.3, Interprocedural Safety)

The IMaxFP solution is a safe, i.e., a lower approximation of the IMOP solution, i.e.

$$\forall\, c_s \in \mathcal{C}\ \forall\, n \in N.\ IMaxFP_{c_s}(n) \sqsubseteq IMOP_{c_s}(n)$$

if the data flow analysis functional $[\![\ ]\!]'$ *is monotonic.*

Theorem (14.1.4.4, Interprocedural Coincidence)

The IMaxFP solution coincides with the IMOP solution, i.e.

$$\forall\, c_s \in \mathcal{C}\ \forall\, n \in N.\ IMaxFP_{c_s}(n) = IMOP_{c_s}(n)$$

if the data flow analysis functional $[\![\ ]\!]'$ *is distributive.*

The 2nd Order Alg. 14.1.5.1 – Preprocess

Input: (1) A flow-graph system S, and (2) an abstract semantics consisting of a data-flow lattice $\mathcal{C}$, and a data-flow functional $[\![\ ]\!]' : E^* \to (\mathcal{C} \to \mathcal{C})$.

Output: Under the assumption of termination (cf. Theorem 14.1.5.4), an annotation of S with functions $[\![\![\, n \,]\!]\!] : \mathcal{C} \to \mathcal{C}$ (stored in *gtr* , which stands for *global transformation*), and $[\![\, e \,]\!] : \mathcal{C} \to \mathcal{C}$ (stored in *ltr* , which stands for *local transformation*) representing the greatest solution of the 2nd order Equation System 14.1.3.1.

Remark: The variable *workset* controls the iterative process. Its elements are nodes of the flow-graph system S. Note that due to the mutual interdependence of the definitions of $[\![\![\ ]\!]\!]$ and $[\![\ ]\!]$ the iterative approximation of $[\![\![\ ]\!]\!]$ is superposed by an interprocedural iteration step, which updates the current approximation of the effect $[\![\ ]\!]$ of call edges. The temporary *meet* stores the result of the most recent meet operation.

A 1st Variant of the *IMaxFP*-Algorithm

- Algorithm 14.1.5.3 uses the semantics functions computed by Algorithm 14.1.5.1 more efficiently.
- Algorithm 14.1.5.1 and 14.1.5.3 constitute a pair of algorithms computing the *IMaxFP* solution, too.
- Replacing Algorithm 14.5.1.2 by Algorithm 14.1.5.3 has no impact on Algorithm 14.1.5.1.
- Unlike Algorithm 14.1.5.2, Algorithm 14.1.5.3 does not iterate over all nodes but only over procedure start nodes. After stabilization of the solution for the start nodes, a single run over all other nodes in the epilogue suffices to compute the *IMaxFP* solution at every node.

Termination

Theorem (14.1.5.4, Termination)

The sequential composition of Algorithm 14.1.5.1 and Algorithm 14.1.5.2 resp. Algorithm 14.1.5.3 terminates with the IMaxFP solution, if the data flow analysis functional $[\![\ ]\!]'$ *is monotonic and the function lattice* $[\mathcal{C} \to \mathcal{C}]$ *satisfies the descending chain condition.*

Note: The descending chain condition on $[\mathcal{C} \to \mathcal{C}]$ implies the descending chain condition on $\mathcal{C}$.

A 2nd Variant of the *IMaxFP*-Algorithm (1)

Partial instead of total computation of the semantics of the procedures:

- Unlike to the previous two algorithm variants, the new variant allows an interleaving of preprocess and main process.
- The computation starts with the main process algorithm.
- If a procedure call is encountered during the iterative process, the preprocess algorithm is started for this procedure and the current data flow fact.
- After completion of the computation of the effect of the procedure for this data flow fact, the main process algorithm is continued with the computed result.

A 2nd Variant of the *IMaxFP*-Algorithm (2)

Note:

- The computation of the semantics of the procedures is performed demand-drivenly.
- The semantics of procedures are only computed as as far as necessary.
- Overall, this results in some efficiency gain in practice, which, however, is difficult to quantify.

Applications

- For the parameterless base setting the specifications of intraprocedural DFA problems can be reused unmodified.
- In order to be effective, the descending chain condition must hold both for the data flow analysis lattice and its corresponding function lattice.
- This condition holds in particular for all bitvector problems (availability of expressions, lifeness of variables, reaching definitions, etc.) but not for simple constants. Therefore, weaker and simpler classes of constants are used interprocedurally, e.g., the set of linear constants.

Outline

We extend our setting by adding

- Value parameters
- Local variables

This requires to adjust our program representations towards

- Flow graph systems (FGS) w/ value parameters and local variables
- Interprocedural flow graphs (IFG) w/ value parameters and local variables

New Phenomena

...related to procedures, value parameters, and local variables.

Conceptually most important:

- Existence of an unlimited number of copies (incarnations) of local variables and value parameters at run-time due to recursive procedures.
- After termination of a recursive procedure call the local variables and value parameters of the proceding not yet finished procedure call become valid again.
- The run-time system handles this phenomena by means of of a run-time stack which stores the activation records of the various procedure incarnations.

For program analysis, we have to take these phenomena into account and to model them properly.

Data Flow Analysis Stacks

Intuitively:

- DFA stacks are a compile-time equivalent of run-time stacks.
- Entries in DFA stacks are data flow facts of an underlying DFA lattics $\mathcal{C}$.
- We denote the set of all non-empty DFA stacks by $STACK$.

14.1.5
14.1.6
14.2

Manipulating DFA Stacks

DFA stacks can be manipulated by:

1. newstack : $\mathcal{C} \rightarrow STACK$
   newstack(c) generates a new DFA stack with entry c.
2. push : $STACK \times \mathcal{C} \rightarrow STACK$
   push stores a new entry on top of a DFA stack.
3. pop : $STACK \rightarrow STACK$
   pop removes the top-most entry of a DFA stack.
4. top : $STACK \rightarrow \mathcal{C}$
   top yields the contents of the top-most entry of a DFA stack w/out modifying the stack.

14.1.6
14.2

Remarks (1)

- The usual stack function emptystack : $\rightarrow STACK$ is replaced by newstack. Empty DFA stacks are not considered since they do not occur in interprocedural DFA.
- push and pop allow to manipulate the top-most entries of a DFA stack. This is different to and less flexible as for run-time stacks but suffices for interprocedural DFA.
- In fact, DFA stacks are only conceptually relevant, i.e., for the specifying, i.e., for the specifying *IMOP* approach but not for the algorithmic *IMaxFP* approach.

14.1.5
14.1.6

Remarks (2)

- Like run-time stacks DFA stacks store that part of the history of a program path that is relevant after finishing a procedure call.
- DFA stack entries can be considered abstractions of the activation records of procedure calls.
- The top-most entry of a DFA stack represents always the currently valid activation record (therefore, DFA stacks are never empty).
- Other than the top-most DFA stack entries represent the activation records of already started but not yet finished procedure calls.

Notations related to DFA Stacks

- $STACK_{\geq i}$ ($STACK_{\leq i}$, etc.), $i \in \mathbb{N}$ denotes the set of all DFA Stacks w/ at last (at most, etc.) i entries (hence $STACK$ equals $STACK_{\geq 1}$.
- $STACK_i$, $i \in \mathbb{N}$, denotes the set of all DFA Stacks w/ exactly i entries.
- ϑ_{stk} denotes the number of entries of the DFA stack stk.
- stk_i, $1 \leq i \leq \vartheta_{stk}$, denotes the ith entry of the DFA stack stk.

The Structure of the Semantic Functions

All semantic functions occurring in interprocedural DFA are an element of the following subsets of the set of all functions $\mathcal{F} =_{df} [\, STACK \to STACK \,]$ on DFA stacks:

- $\mathcal{F}_{ord}$
- $\mathcal{F}_{psh}$
- $\mathcal{F}_{pop}$

These sets of functions are given by:

$$\mathcal{F}_{ord} =_{df} \{\, f \in \mathcal{F} \mid \forall\, stk \in STACK.\ \mathrm{pop}(f(stk)) = pop(stk) \,\}$$

$$\mathcal{F}_{psh} =_{df} \{\, f \in \mathcal{F} \mid \forall\, stk \in STACK.\ \mathrm{pop}(f(stk)) = stk \,\}$$

$$\mathcal{F}_{pop} =_{df} \{\, f \in \mathcal{F} \mid \forall\, stk \in STACK_{\geq 2}.\ \mathrm{pop}(f(stk)) = \mathrm{pop}(\mathrm{pop}(stk)) \,\}$$

The Significant Part of DFA Functions

Only the two top-most entries of DFA stacks are modified by DFA functions. This gives rise to the following definition:

Definition (14.2.1.4, Significant Part)

- $f \in \mathcal{F}_{ord} \cup \mathcal{F}_{psh}$: Then $f_s : \mathcal{C} \to \mathcal{C}$ is defined by:
  $f_s(c) =_{df} \mathrm{top}(f(\mathrm{newstack}(c)))$
- $f \in \mathcal{F}_{pop}$: Then $f_s : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ is defined by:
  $f_s(c_1, c_2) =_{df} \mathrm{top}(f(\mathrm{push}(\mathrm{newstack}(c_1), c_2)))$
  (Note that $\mathcal{C} \times \mathcal{C}$ is a lattice, if $\mathcal{C}$ is a lattice.)

We have:

Lemma (14.2.1.5)

1. $\forall\, e \in E^* \backslash E_r^*.\ [\![\, e \,]\!]_s^* = [\![\, e \,]\!]'$
2. $\forall\, e \in E_r^*\ \forall\, c_1, c_2 \in \mathcal{C} \times \mathcal{C}.\ [\![\, e \,]\!]_s^* = \mathcal{R}_e(c_1, [\![\, e \,]\!]'(c_2))$

S-Monotonicity, S-Distributivity

Definition (14.2.1.7, S-Mon., S-Distrib.)

A DFA function $f \in \mathcal{F}_{ord} \cup \mathcal{F}_{psh} \cup \mathcal{F}_{pop}$ is

1. s-monotonic iff f_s is monotonic
2. s-distributive iff f_s is distributive

Conventions

In the following

- we consider s-monotonicity and s-distributivity as generalizations of the usual monotonicity and distributivity.

To this end, we

- identify lattice elements with their representation as a DFA stack with just a single entry.
- extend the meet and join operation $\sqcap$ and $\sqcup$ as follows to (the top most entries of) DFA stacks:

$$\bigsqcap STK =_{df} \text{newstack}(\bigsqcap\{top(stk) \mid stk \in STK\})$$

$$\bigsqcup STK =_{df} \text{newstack}(\bigsqcup\{top(stk) \mid stk \in STK\})$$

Preliminaries

Let

- Id_{STACK} denote the identity on $STACK$, and
- $\sqcap$ the pointwise meet-operation on $\mathcal{F}_{ord}$

Note:

- $\forall\, f, f' \in \mathcal{F}_{ord}.\ f \sqcap f' =_{df} f'' \in \mathcal{F}_{ord}$ with $\forall\, stk \in STACK.\ \ topl(f''(stk)) = \mathrm{top}(f(stk)) \sqcap \mathrm{top}(f'(stk))$.
- "$\sqcap$" induces an inclusion relation "$\sqsubseteq$" on $\mathcal{F}_{ord}$ by: $f \sqsubseteq f'$ gdw. $f \sqcap f' = f$.

The $IMaxFP_{Stk}$ Approach (1)

Stage 1: Preprocess – Computing the Semantics of Procedures:

The 2nd Order Equation System 14.2.3.1

$$[\![n]\!] = \begin{cases} Id_{STACK} & \text{if } n \in start(S) \\ \bigsqcap\{[\![(m,n)]\!] \circ [\![m]\!] \mid m \in pred_{flowGraph(n)}(n)\} & \\ & \text{otherwise} \end{cases}$$

and

$$[\![e]\!] = \begin{cases} [\![e]\!]^* & \text{if } e \in E \backslash E_{call} \\ [\![e_r]\!]^* \circ [\![end(callee(e))]\!] \circ [\![e_c]\!]^* & \text{otherwise} \end{cases}$$

14.1.5
14.1.6

The $IMaxFP_{Stk}$ Approach (2)

The 1st Order $IMaxFP_{Stk}$ Equation System 14.2.3.2:

$$inf(n) = \begin{cases} \text{newstack}(c_{\mathbf{s}}) & \text{if } n = \mathbf{s}_0 \\ \bigsqcap \{ [\![e_c]\!]^*(inf(src(e))) \mid e \in caller(flowGraph(n)) \} & \\ & \text{falls } n \in start(S) \setminus \{\mathbf{s}_0\} \\ \bigsqcap \{ [\![(m,n)]\!](inf(m)) \mid m \in pred_{flowGraph(n)}(n) \} & \\ & \text{otherwise} \end{cases}$$

The $IMaxFP_{Stk}$ Solution:

$$\forall\, c_{\mathbf{s}} \in \mathcal{C}\ \forall\, n \in N.\ IMaxFP_{Stk\,c_{\mathbf{s}}}(n) =_{df} inf^*_{c_{\mathbf{s}}}(n)$$

Towards the Main Results

Important:

Lemma (14.2.4.1)

For all $n \in N$ the semantic functions $[\![e]\!]^*$, $e \in E^*$, are

1. *s-monotonic:* $[\![n]\!] \sqsubseteq imop_n$
2. *s-distributive:* $[\![n]\!] = imop_n$

where $imop_n : N \to (STACK \to STACK)$ denotes a functional that is defined by:

$$\forall\, n \in N.\ imop_n =_{df} \begin{cases} Id_{STACK} & \text{if } n \in start(S) \\ \bigsqcap\{[\![p]\!]^* \mid p \in \mathbf{CIP}[start(flowGraph(n)), n]\} & \text{otherwise} \end{cases}$$

Main Results – 1st Stage

Safety and coincidence results of the 2nd order 1st stage analysis:

Theorem (14.2.4.2, 2nd-Order)

For all $e \in E_{call}$ *we have:*

1. $[\![e]\!] \sqsubseteq \bigsqcap\{[\![p]\!]^* \mid p \in \mathbf{CIP}[src(e), dst(e)]\}$, *if* $[\![\ ]\!]^*$ *is s-monotonic.*
2. $[\![e]\!] = \bigsqcap\{[\![p]\!]^* \mid p \in \mathbf{CIP}[src(e), dst(e)]\}$, *if* $[\![\ ]\!]^*$ *is s-distributive.*

where the mappings *src* and *dst* yield the start and final node of an edge.

Main Results – 2nd Stage

Safety and coincidence results of the 1st order 2nd stage analysis:

Theorem (14.2.4.3, Interprocedural Safety)

The $IMaxFP_{Stk}$ *solution is a lower (i.e., safe) approximation of the* $IMOP_{Stk}$ *solution, i.e.*

$$\forall\, c_s \in \mathcal{C}\ \forall\, n \in N.\ IMaxFP_{Stk\,c_s}(n) \sqsubseteq IMOP_{Stk\,c_s}(n)$$

if $[\![\ ]\!]^*$ *is s-monotonic.*

Theorem (14.2.4.4, Interprocedural Coincidence)

The $IMaxFP_{Stk}$ *solution coincides with the* $IMOP_{Stk}$ *solution, i.e.*

$$\forall\, c_s \in \mathcal{C}\ \forall\, n \in N.\ IMaxFP_{Stk\,c_s}(n) = IMOP_{Stk\,c_s}(n)$$

if $[\![\ ]\!]^*$ *is s-distributive.*

Algorithms

- The algorithms of Chapter 14.1.5 can straightforwardly be extended to stack-based functions.
- This way we receive
  - the standard variant of pre- and post-process
  - the more efficient variant of pre- and functional main process.
  - a demand-driven "by-need" variant.
- In the following we present another stackless variant. The clou of this variant is that stacks have at most 2 entries during analysis time.

  Therefore, a single temporary storing the temporarily existing stack entry during procedure calls is sufficient for the implementation.

The Stackless 2nd Order Algorithm 14.2.5.1 – Preprocess

Input: (1) A flow-graph system S, and (2) an abstract semantics consisting of a data-flow lattice $\mathcal{C}$, and a data-flow functional $[\![\ ]\!]' : E^* \to (\mathcal{C} \to \mathcal{C})$.

Output: Under the assumption of termination (cf. Theorem 14.2.5.4), an annotation of S with functions $[\![\![\, n \,]\!]\!] : \mathcal{C} \to \mathcal{C}$ (stored in *gtr*, which stands for *global transformation*), and $[\![\, e \,]\!] : \mathcal{C} \to \mathcal{C}$ (stored in *ltr*, which stands for *local transformation*) representing the greatest solution of Equation System 14.2.3.1.

Remark: The variable *workset* controls the iterative process. Its elements are nodes of the flow-graph system S. Note that due to the mutual interdependence of the definitions of $[\![\![\ ]\!]\!]$ and $[\![\ ]\!]$ the iterative approximation of $[\![\![\ ]\!]\!]$ is superposed by an interprocedural iteration step, which updates the current approximation of the effect $[\![\ ]\!]$ of call edges. The temporary *meet* stores the result of the most recent meet operation.

Termination

Theorem (14.2.5.4, Termination)

The sequential composition of Algorithm 14.2.5.1 and Algorithmus 14.2.5.2 resp. Algorithm 14.2.5.3 terminates with the IMaxFP$_{Stk}$ solution, if the DFA functional $[\![\ ]\!]'$ and the return functional $\mathcal{R}$ are monotonic and the lattice of functions $[\mathcal{C} \to \mathcal{C}]$ satisfies the descending chain condition.

Note: If $[\mathcal{C} \to \mathcal{C}]$ satisfies the descending chain condition, then $\mathcal{C}$ does so as well.

Reference Parameters

Intuitively:

- The effect of reference parameters is encoded in the local semantic functionals of the application problems.
- Reference parameters can thus be handled and computed by suitable preprocess computing may and must aliases of variables and parameters.
- The computed alias information is then fed into the definitions of the local semantics functions of the application problems (cf. Chapter 14.4)

14.1.5
14.1.6

Procedure Parameter

Intuitively:

- A formal procedure call is replaced by the set of all ordinary procedure calls that it may call.
- This set of procedures can be computed by a suitable preprocess; dependingy on the program or programming language class this can be either a safe approximation or an exact solution.
- The computed calling information for formal procedure call reduces then the analysis of programs w/ formal procedure calls to the analysis of programs w/out formal procedure calls.

Static Procedure Nesting

Various variants are possible:

- De-nesting of procedures by a suitable preprocess; this way the analysis of programs w/ static procedure nesting is reduced to analysing programs w/out static procedure nesting.
- Taking into account the effect of relatively global variables in the definition of the local semantics functions of the application problems.

Preliminaries

In the following we assume:

- No static procedure nesting, no procedure parameters.
- $MstAliases_G(v)$ und $MayAliases_G(v)$ denote the sets of must-Aliases and may-Aliases different from v.

These notions can straightforward be extended to terms t:

- A term t' is a must-alias (may-alias) of t, if t' results from t by replacing of variables by variables that are must-aliases (may-aliases) of each other.

This allows us to feed alias information in a parameterized fashion into the definitions of DFA functionals and return functionals and to take their effects during the analysis into account.

Notations (1)

- $GlobVar(S)$: the set of *global variables* of S, i.e., the set of variables which are declared in the main program of S. They are accessible in each procedure of S.
- $Var(t)$: the set of variables occurring in t.
- $LhsVar(e)$: the left hand side variable of the assignment of edge e.
- $GlobId(t)$ and $LocId(t)$: abbreviations of $GlobVar(S) \cap Var(t)$ and $Var(t) \setminus GlobVar(S)$.

14.1.6

Notations (2)

- $NoGlobalChanges : E^* \to \mathbb{B}$: indicates that if a variable $v \in Var(t)$ is modified by e, then this modification will not be visible after finishing the call as the relevant memory location of v is local for the currently active call.
- $PotAccessible : S \to \mathbb{B}$: indicates that the memory locations of all variables $v \in Var(t)$, which are accessible immediately before entering G remain accessible after entering it, either by referring to v itself or by referring to one of its must-aliases.

Local Predicates

The definition of the preceding functions relies on the predicates $Transp_{LocId}$ and $Transp_{GlobId}$ that are defined as follows:

$$Transp_{LocId}(e) =_{df} LocId(t) \cap MayAliases_{flowGraph(e)}(LhsVar(e)) = \emptyset$$

$$Transp_{GlobId}(e) =_{df} GlobId(t) \cap (LhsVar(e) \cup MayAliases_{flowGraph(e)}(LhsVar(e))) = \emptyset$$

This allows us to define:

$$\forall\, e \in E^*.\ NoGlobalChanges(e) =_{df} \begin{cases} \textbf{true} & \text{if } e \in E_c^* \cup E_r^* \\ Transp_{LocId}(n) \wedge Transp_{GlobId}(n) & \text{otherwise} \end{cases}$$

14.1.2
14.1.3
14.1.4
14.1.5
14.1.6

Parameterized Local Predicates (2)

Intuitively:

- $A\text{-}Comp_e$ is true for t, if t itself (i.e., $Comp_e$) or one of its must-aliases is computed at edge e (i.e., $Comp_e^{MstAl}$).
- $A\text{-}Transp_e$, $e \in E^* \backslash E^*_{call}$, is true, if neither an operand of t (i.e., $Transp_e$) nor one of its may-aliases is modified by the statement at edge e (i.e., $Transp_e^{MayAl}$).
- For call and return edges $e \in E^*_{call}$, $A\text{-}Transp_e$ is true, if no operand of t is modified (i.e., $Transp_e$). This makes the difference between ordinary assignments and reference parameters and parameter transfers to reference parameters; the latter are updates of pointers that leave the memory invariant except of that update.

Interprocedural Simple Constants

Local Abstract Semantics:

1. Data flow lattice:
   $(\mathcal{C}, \sqcap, \sqcup, \sqsubseteq, \bot, \top) =_{df} (\Sigma_X, \sqcap, \sqcup, \sqsubseteq, \sigma_\bot, \sigma_{failure})$
2. Data flow functional: $[\![\ ]\!]'_{sc} : E \to (\Sigma_X \to \Sigma_X)$ defined by
   $\forall\, e \in E.\ [\![\, e \,]\!]'_{sc} =_{df} \theta_e$
3. Return functional: $\mathcal{R}_{sc} : E_{call} \to (\Sigma_X \times \Sigma_X \to \Sigma_X)$
   defined by

   $$\forall\, e \in E_{call}\ \forall\, (\sigma_1, \sigma_2)) \in \Sigma_X \times \Sigma_X.\ \mathcal{R}_{sc}(e)(\sigma_1, \sigma_2) =_{df} \sigma_3$$

   where

   $$\forall\, x \in Var.\ \sigma_3(x) =_{df} \begin{cases} \sigma_2(x) & \text{if } x \in GlobVar(S) \\ \sigma_1(x) & \text{otherwise} \end{cases}$$

Problems and Solutions/Work-Arounds

In practice

- the preceding analysis specification for simple interprocedural constants does not induce a terminating analysis since the lattice of functions does not satisfy the descending chain condition
- thus simpler constant propagation problems are considered like copy constants and linear constants.

Copy Constants and Linear Constants

A term is a

- copy constant at a program point, if it is a source-code constant or an operator-less term that is itself a copy constant
- linear constant at a program point, if it is a source-code constant or of the form $a * x + b$ w/ a, b source-code constants and x a linear constant.

14.1.3
14.1.4
14.1.5
14.1.6

Interprocedural Copy Constants (1)

The specification of copy constants is based on the following simpler evaluation function of terms:

$$\mathcal{E}_{cc} : \mathbf{T} \to (\Sigma_X \to \mathbf{D})$$

$\mathcal{E}_{cc}$ is undefined for the failure state $\sigma_{failure}$; otherwise it is defined as follows:

$$\forall\, t \in \mathbf{T}\ \forall\, \sigma \in \Sigma.\ \mathcal{E}_{cc}(t)(\sigma) =_{df} \begin{cases} \sigma(x) & \text{if } t = x \in \mathbf{V} \\ I_0(c) & \text{if } t = c \in \mathbf{C} \\ \bot & \text{otherwise} \end{cases}$$

Note that Σ_X is analogously to $\mathcal{B}_X$ extended by an artificial top-element.

Interprocedural Copy Constants (2)

- Replacing θ_ι in $\mathcal{E}$ by $\mathcal{E}_{cc}$ yields the data flow analysis functional $[\![\ ]\!]'_{cc}$.
- Replacing of $[\![\ ]\!]'_{sc}$ by $[\![\ ]\!]'_{cc}$ yields the definition of the local abstract semantics of interprocedural copy constants.

Interprocedural Copy Constants (3)

Note:

- The number of source-code constants is finite.
- Hence, the lattice of functions that belongs to the relevant sublattice Σ_{cc_X} of Σ_X satisfies the descending chain condition.
- Thus, the *IMaxFP* algorithm terminates.
- Unlike as interprocedural simple constants are copy constants distributive; thus, the $IMaxFP_{Stk}$ solution and the $IMOP_{Stk}$ solution coincide.

Aliasing Everywhere

Answers to the question "What is an alias?" in different areas:

- A short, easy to remember name created for use in place of a longer, more complicated name; commonly used in e-mail applications. Also referred to as a "nickname".
- A hostname that replaces another hostname, such as an alias which is another name for the same Internet address. For example, www.company.com could be an alias for server03.company.com.
- A feature of UNIX shells that enables users to define program names (and parameters) and commands with abbreviations. (e.g. alias ls 'ls -l')
- In MGI (Mouse Genome Informatics), an alternative symbol or name for part of the sequence of a known gene that resembles names for other anonymous DNA segments. For example, D6Mit236 is an alias for Cftr.

Aliasing in Programs

programs aliasing occurs when there exists more than one access path to a storage location.

An access path is the l-value of an expression that is constructed from variables, pointer dereference operators, and structure field operation operators.

Examples of Different Forms of Aliasing (1)

Fortran 77

EQUIVALENCE statement can be used to specify that two or more scalar variables, array variables, and/or contiguous portions of array variables begin at the same storage location.

Pascal,Modula 2/3,Java

- Variable of a reference type is restricted to have either the value nil/null or to refer to objects of a particular specified type.
- An object may be accessible through several references at once, but it cannot both have its own variable name *and* be accessible through a pointer.

Examples of Different Forms of Aliasing (2)

C/C++

- The union type specifier allows to create static aliases. A union type may have several fields declared, all of which overlap in (= share) storage.
- It is legal to compute the address of an object with the & operator (statically, automatically, or dynamically allocated).
- Allows arithmetic on pointers and considers it equivalent to array indexing

Relevance of Alias Analysis to Optimization

Alias analysis refers to the determination of storage locations that may be accessed in two or more ways.

- Ambiguous memory references interfere with an optimizer's ability to improve code.
- One major source of ambiguity is the use of pointer-based values.

  Goal: determine for each pointer the set of memory locations to which it may refer.

Without alias analysis the compiler must assume that each pointer can refer to any addressable value, including

- any space allocated in the run-time heap
- any variable whose address is explicitly taken
- any variable passed as a call-by-reference parameter

Characterization of Aliasing

Flow-insensitive information

Binary relation on the variables in a procedure, $alias \in Var \times Var$ such that x *alias* y if and only if x and y

- may possibly at different times refer to the same memory location.
- must throughout the execution of the procedure refer to the same memory location.

Flow-sensitive information

A function from program points and variables to sets of abstract storage locations. $alias(p, v) = Loc$ means that at program point p variable v

- may refer to any of the locations in Loc.
- must refer to the location $l \in Loc$ with $|Loc| \leq 1$.

Questions about Heap Contents (1)

Execution State

Let *execution state* mean the set of cells in the heap, the connections between them (via pointer components of heap cells) and the values of pointer variables in the store.

NULL pointers (Question 1)

Does a pointer variable or a pointer component of a heap cell contain NULL at the entry to a statement that dereferences the pointer or component?

- Yes (for every state). Issue an error message
- No (for every state). Eliminate a check for NULL.
- Maybe. Warn about the potential NULL dereference.

Questions about Heap Contents (2)

Memory leak (Question 2)

Does a procedure or a program leave behind unreachable heap cells when it returns?

- Yes (in some state). Issue a warning.

Aliasing (Question 3)

Do two pointer expressions reference the same heap cell?

- Yes (for every state).
  - trigger a prefetch to improve cache performance
  - predict a cache hit to improve cache behavior prediction
  - increase the sets of uses and definitions for an improved liveness analysis
- No (for every state). Disambiguate memory references and improve program dependence information.

Questions about Heap Contents (3)

Sharing (Question 4)

Is a heap cell shared? (within the heap)

- Yes (for some state). Warn about explicit deallocation, because the memory manager may run into an inconsistent state.
- No (for every state). Explicitly deallocate the heap cell when the last pointer to ceases to exist.

Reachability (Question 5)

Is a heap cell reachable from a specific variable or from any pointer variable?

- Yes (for every state). Information for program verification.
- No (for every state). Insert code at compile time that collects unreachable cells at run-time.

Questions about Heap Contents (4)

Disjointness (Question 6)

Do two data structures pointed to by two distinct pointer variables ever have common elements?

- No (for every state). Distribute disjoint data structures and their computations to different processors.

Cyclicity (Question 7)

Is a heap cell part of a cycle?

- No (for every state). Perform garbage collection of data structures by reference counting. Process all elements in an acyclic linked list in a doall-parallel fashion.

Shape Analysis

Aim of Shape Analysis

The aim of shape analysis is to determine a finite representation of heap allocated data structures which can grow arbitrarily large.

It can determine the possible shapes data structures may take such as:

- lists
- trees
- directed acyclic graphs
- arbitrary graphs
- properties such as whether a data structure is or may be cyclic

As example we shall discuss a precise shape analysis (from PoPA Ch 2.6) that performs strong update and uses shape graphs to represent heap allocated data structures. It emphasises the analysis of list like data structures.

Strong Update

Here "strong" means that an update or nullification of a pointer expression allows one to *remove* (kill) the existing binding before adding a new one (gen).

We shall study a powerful analysis that achieves

- Strong nullification
- Strong update

for destructive updates that destroy (overwrite) existing values in pointer variables and in heap allocated data structures in general.

Examples:

- $[x := nil]^\ell$
- $[x.sel_1 := y.sel_2]^\ell$

Extending the WHILE Language

We extend the WHILE-language syntax with constructs that allow to create cells in the heap.

- the cells are structured and may contain values as well as pointers to other cells
- the data stored in cells is accessed via selectors; we assume that a finite and non-empty set Sel of selector names is given:

$$sel \in \mathsf{Sel} \qquad \text{selector names}$$

- we add a new syntactic category

$$p \in \mathsf{PExp} \qquad \text{pointer expressions}$$

- op_r is extended to allow for testing of equality of pointers
- unary operations op_p on pointers (e.g. is-null) are added

Abstract Syntax of Pointer Language

The syntax of the while language is extended to have:

$$
\begin{array}{lcl}
p & ::= & x \mid x.sel \mid \text{null} \\
a & ::= & x \mid n \mid a_1 \; op_a \; a_2 \\
b & ::= & \text{true} \mid \text{false} \mid \text{not } b \mid b_1 \; op_b \; b_2 \mid a_1 \; op_r \; a_2 \\
S & ::= & [\text{p:=a}]^\ell \mid [\text{skip}]^\ell \\
 & & \mid \text{if } [b]^\ell \text{ then } S_1 \text{ else } S_2 \\
 & & \mid \text{while}[b]^\ell \text{ do } S \text{ od} \\
 & & \mid [\text{new } (p)]^\ell \\
 & & \mid S_1; S_2
\end{array}
$$

In the case where p contains a selector we have a destructive update of the heap. Statement new creates a new cell pointed to by p.

Shape Graphs

We shall introduce a method for combining the locations of the semantics into a finite number of *abstract locations*.

The analysis operates on shape graphs (S, H, is) consisting of:

- an abstract state, S (mapping variables to abstract locations)
- an abstract heap, H (specifying links between abstract locations)
- sharing information, is, for the abstract locations.

The last component allows us to recover some of the imprecision introduced by combining many locations into one abstract location.

Abstract Locations

The *abstract locations* have the form n_X where X is a subset of the variables of $\mathsf{Var}_\star$:

$$\mathsf{ALoc} = \{n_X \mid X \subseteq \mathsf{Var}_\star\}$$

A shape graph contains a subset of the abstract locations of ALoc

The abstract location $n_\emptyset$ is called the *abstract summary location* and represents all the locations that cannot be reached directly from the state without consulting the heap.

Clearly n_X and $n_\emptyset$ represent disjoint sets of locations when $X \neq \emptyset$.

Invariant 1: If two abstract locations n_X and n_Y occur in the same shape graph then either $X = Y$ or $X \cap Y = \emptyset$. (i.e. two distinct abstract locations n_X and n_Y always represent disjoint sets of locations)

Chap. 16

Abstract State

The abstract state, S, maps variables to abstract locations. To maintain the naming convention for abstract locations we shall ensure that:

Invariant 2: If x is mapped to n_X by the abstract state then $x \in X$.

From Invariant 1 it follows that there will be at most one abstract location in the (same) shape graph containing a given variable.

We shall only be interested in the shape of heap so we shall not distinguish between integer values, nil-pointers, and uninitialized fields; hence we can view the abstract state as an element of

$$\mathsf{S} \in \mathsf{AState} = \mathcal{P}\mathsf{Var}_\star \times \mathsf{ALoc}$$

15.3
Chap. 16

Abstract Heap

The abstract heap, H, specifies the links between the abstract locations.

The links will be specified by triples (n_V, sel, n_W) and formally we take the abstract heap as an element of

$$\mathsf{H} \in \mathsf{AHeap} = \mathcal{P}\mathsf{ALoc} \times \mathsf{Sel} \times \mathsf{ALoc}$$

where we again not distinguish between integers, nil-pointers and uninitialized fields.

Invariant 3: Whenever (n_V, sel, n_W) and (n_V, sel, n'_W) are in the abstract heap then either $V = \emptyset$ or $W = W'$.

Thus the target of a selector field will be uniquely determined by the source unless the source is the abstract summary location $n_\emptyset$.

Sharing Information

The idea is to specify a subset, is, of the abstract locations that represents locations that are shared due to pointers *in* the heap:

- an abstract location n_X will be included in is if it represents a location that is the target of more than one pointer in the heap.

In the case of the abstract summary location, $n_\emptyset$, the explicit sharing information clearly gives extra information:

- if $n_\emptyset \in$ is then there might be a location represented by $n_\emptyset$ that is the target of two or more heap pointers.
- if $n_\emptyset \notin$ is then all the locations of represented by $n_\emptyset$ will be the target of at most one heap pointer.

Sharing Information Invariants (1)

We shall impose two invariants to ensure that information in the sharing component is also reflected in the abstract heap.

The first ensures that information in the sharing component is also reflected in the abstract heap:

Invariant 4: If $n_X \in$ is then either

a) $(n_\emptyset, sel, n_X)$ is in the abstract heap for some sel, or

b) there exist two distinct triples (n_V, sel_1, n_X) and (n_W, sel_2, n_X) in the abstract heap (that is either $sel_1 \neq sel_2$ or $V \neq W$).

- case 4a) means that there might be several locations represented by $n_\emptyset$ that point to n_X
- case 4b) means that two distinct pointers (with different source or different selectors) point to n_X.

Chap. 12
Chap. 13
Chap. 14
Chap. 15
15.1
15.2
15.3
Chap. 16

Sharing Information Invariants (2)

The second invariant ensures that sharing information present in the abstract heap is also reflected in the sharing component:

Invariant 5: Whenever there are two distinct triples (n_V, sel_1, n_X) and (n_W, sel_2, n_X) in the abstract heap and $n_X \neq n_\emptyset$ then $n_X \in$ is.

This invariant takes care of the situation where n_X represents a single location being the target of two or more heap pointers.

Note that invariant 5 is the "inverse" of invariant 4(b).

We have no "inverse" of invariant 4(a) - the presence of a pointer from $n_\emptyset$ to n_X gives no information about sharing properties of n_X that are represented in is.

Compatible Shape Graphs

A shape graph is a triple $(\mathsf{S}, \mathsf{H}, \mathsf{is})$:

$$\begin{aligned} \mathsf{S} \in \mathsf{AState} &= \mathcal{P}\mathsf{Var}_\star \times \mathsf{ALoc} \\ \mathsf{H} \in \mathsf{AHeap} &= \mathcal{P}\mathsf{ALoc} \times \mathsf{Sel} \times \mathsf{ALoc} \\ \mathsf{is} \in \mathsf{IsShared} &= \mathcal{P}\mathsf{ALoc} \end{aligned}$$

where $\mathsf{ALoc} = \{n_X \mid X \subseteq \mathsf{Var}_\star\}$.

A shape graph is a compatible shape graph if it fulfills the five invariants, 1-5, presented above. The set of compatible shape graphs is denoted

$$\mathsf{SG} = \{(\mathsf{S}, \mathsf{H}, \mathsf{is}) \mid (\mathsf{S}, \mathsf{H}, \mathsf{is}) \text{ is compatible}\}$$

Complete Lattice of Shape Graphs

The analysis, to be called *Shape*, will operate over *sets* of compatible shape graphs, i.e. elements of $\mathcal{P}$SG.
Since $\mathcal{P}$SG is a power set it is trivially a complete lattice with

- ordering relation $\sqsubseteq$ being $\subseteq$
- combination operator $\sqcap$ being $\cup$ (may analysis)

$\mathcal{P}$SG is finite because SG $\subseteq$ AState $\times$ AHeap $\times$ IsShared and all of AState, AHeap, IsShared are finite.

The analysis will be specified as an instance of a Monotone Framework with the complete lattice of properties being $\mathcal{P}$SG, and as a forward analysis.

Transfer Functions

The transfer function $f_\ell^{\mathsf{SA}} : \mathcal{P}\mathsf{SG} \to \mathcal{P}\mathsf{SG}$ has the form

$$f_\ell^{SA}(\mathsf{SG}) = \bigcup \{\phi_\ell^{\mathsf{SA}}((\mathsf{S}, \mathsf{H}, \mathsf{is})) \mid (\mathsf{S}, \mathsf{H}, \mathsf{is}) \in \mathsf{SG}\}$$

where ϕ_ℓ^{SA} specifies how a *single* shape graph (in $\mathsf{Shape}_\circ(\ell)$) may be transformed into a *set* of shape graphs (in $\mathsf{Shape}_\bullet(\ell)$.

The functions ϕ_ℓ^{SA} for the statements

x := a	x := y	x := y.sel
x.sel := a	x.sel := y	x.sel := y.sel

(illustrated by example)

transform a shape graph into a set of different shape graphs.

The transfer functions for other statements and expressions are specified by the identity function.

Reverse List: Established Properties

For the list reversal program shape analysis can detect that at the beginning of each iteration of the loop the following properties hold:

Invariant 1: Variable x points to an unshared, acyclic, singly linked list.

Invariant 2: Variable y points to an unshared, acyclic, singly linked list, and variable t may point to the second element of the y-list (if such an element exists).

Invariant 3: The lists pointed to by x and y are disjoint.

Drawbacks and Improvements

An improved version, on which the discussed analysis is based on, can be found in [SRW'98]:

- Operates on a single shape graph instead of sets of shape graphs
- Merges sets of compatible shape graphs in one summary shape graph
- Uses various mechanisms for extracting parts of individual compatible shape graphs
- Avoids the exponential factor in the cost of the discussed analysis

The sharing component of the shape graphs is designed to detect list-like properties:

- It can be replaced by other components detecting other shape properties [SRW'02, CDH Ch 5]

Object Layout and Method Invocation

The memory layout of an object and how the layout supports dynamic dispatch are crucial factors for performance.

- Single Inheritance
  - with and without virtual dispatch table (i.e., direct calling guarded by a type test)
- Multiple Inheritance
  ...various techniques with different compromises
  - embedding superclasses
  - trampolines
  - table compression

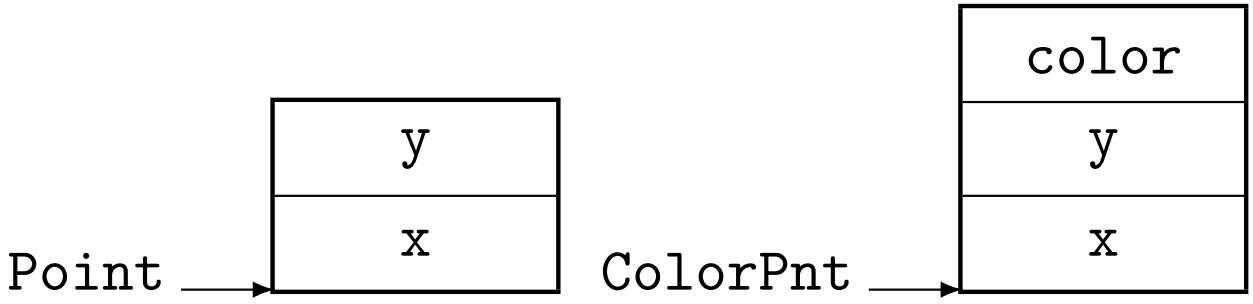
Single Inheritance Layout

```
class Point {
    int x, y;
}
```

```
class ColorPnt extends Point {
    int color;
}
```



- Memory layout of an object of a superclass is a prefix of the memory layout of an object of the subclass.
- Instance variables access requires just one load or store instruction.

Invocation of Virtual Methods with vtbl

- Dynamic dispatching using a vtbl has the advantage of being fast and executing in constant time.
- It is possible to add new methods and to override methods.
- Each method is assigned a fixed offset in the virtual method table (vtbl).
- Method invocation is just three machine code instructions:

```
LDQ vtblptr,(obj)            ; load vtbl pointer
LDQ mptr,method(vtblptr)     ; load method pointer
JSR (mptr)                   ; call method
```

- One extra word of memory is needed in each object for the pointer to the virtual method table (vtbl).

Dispatch Without Virtual Method Tables

Despite the use of branch target caches, indirect branches are expensive on modern architectures.

The pointer to the class information and virtual method table is replaced by a type identifier:

- A type identifier is an integer representing the type of the object.
- It is used in a dispatch function which searches for the type of the receiver.
- Example: SmallEiffel (binary search).
- Dispatch functions are shared between calls with the same statically determined set of concrete types.
- In the dispatch function a direct branch to the dispatched method is used (or it is inlined).

Chap. 12
Chap. 13
Chap. 14
Chap. 15
Chap. 16
16.1
16.1.1
16.1.2

Example

Let type identifiers T_A, T_B, T_C, and T_D be sorted by increasing number. The dispatch code for calling $x.f$ is:

if $id_x \leq T_B$ **then**
  if $id_x \leq T_A$ **then** $f_A(x)$
  else $f_B(x)$
else if $id_x \leq T_C$ **then** $f_C(x)$
  else $f_D(x)$

Comparison with dispatching using a virtual method table:

- Empirical study showed that for a method invocation with three concrete types, dispatching with binary search is between 10% and 48% faster.
- For a megamorphic call with 50 concrete types, the performance is about the same.

Multiple Inheritance

- Extending the superclasses as in single inheritance does not work anymore.
- Fields of superclass are embedded as contiguous block.
- Embedding allows fast access to instance variables exactly as in single inheritance.
- Garbage collection becomes more complex because pointers also point into the middle of objects.

Dynamic Dispatching for Embedding

- Allows fast access to instance variables exactly as with single inheritance.
- For every superclass
  - virtual method tables have to be created.
  - multiple *vtbl* pointers are included in the object.
- The object pointer is adjusted to the embedded object whenever explicit or implicit pointer casting occurs (assignments, type casts, parameter and result passing).

Pointer Adjustment and Adjustment Offset

Pointer adjustment has to be suppressed for casts of null pointers:

```
Colored col; ColorPnt cp; ...;
col = cp;  // if (cp!=null)col=(Colored)((int*)cp+3)
```

Problem with implicit casts from actual receiver to formal receiver

- Caller has no type info of formal receiver in the callee.
- Callee has no type info of actual receiver of the caller.
- Therefore this type info has to be stored as an adjustment offset in the vtbl.

Chap. 14
Chap. 15
Chap. 16
16.1
16.1.1
16.1.2
16.2

Method Invocation with vtbl

Method invocation now takes 4 to 5 machine instructions (depending on the architecture).

```
LD  vtblptr,(obj)                ; load vtbl pointer
LD  mptr,method_ptr(vtblptr)     ; load method pointer
LD  off,method_off(vtblptr)      ; load adjustment offset
ADD obj,off,obj                  ; adjust receiver
JSR (mptr)                       ; call method
```

This overhead in table space and program code is even necessary when multiple inheritance is not used (in the code).

Furthermore, adjustments to the remaining parameters and the result are not possible.

16.1.2
16.2

Trampoline

To eliminate much of the overhead a small piece of code, called trampolin is inserted that performs the pointer adjustments and the jumps to the original code.

The advantages are

- smaller table size (no storing of an offset)
- fast method invocation when multiple inheritance is not used
  - the same dispatch code as in single inheritance

The method pointer `setcolorptr` in the virtual method table of `Colorpoint` would (instead) point to code which adds 3 to the receiver before jumping to the code of method `setcolor`:

```
ADD obj,3,obj                    ; adjust receiver
BR  setcolor                     ; call method
```

Lookup at Compile-Time

Invoking a method requires looking up the address of the method and passing control to it.

In some cases, the lookup may be performed at compile-time:

- There is only one implementation of the method in the class and its subclasses.
- The language provides a declaration that forces the call to be non-virtual.
- The compiler has performed static analysis that can determine that a unique implementation is *always* called at a particular call site.

In other cases, a runtime lookup is required.

16.2

Dispatch Table

In principle the lookup can be implemented as indexing a two-dimensional table. A number is given to

- each method in the program
- each class in the program

The method call

```
result = obj.m(a1,a2);
```

can be implemented by the following three actions:

1. Fetch a pointer to the appropriate row of the dispatch table from the object `obj`.
2. Index the dispatch table row with the method number.
3. Transfer control to the address obtained.

Dispatch Table Compression (1)

- Virtual Tables
  - Effective method for statically typed languages.
  - Methods can be numbered compactly for each class hierarchy to leave no unused entries in each vtbl.
- Row Displacement Compression
  - Idea: combine all rows into a single very large vector.
  - It is possible to have rows overlapping as long as an entry in one row corresponds to empty entries in the other rows.
  - Greedy algorithm: place first row; for all subsequent rows: place on top and shift right if conflicts exist.
  - Unchanged: implementation of method invocation.
  - Penalty: verify class of current object at the beginning of any method that can be accessed via more than one row.

Dispatch Table Compression (2)

- Selector Coloring Compression
  - Graph coloring: two rows can be merged if no column contains different method addresses for the two classes.
  - Graph: one node per class; an edge connects two nodes if the corresponding classes provide different implementations for the same method name.
  - Coloring: each color corresponds to the index for a row in the compressed table.
  - Each object contains a reference to a possibly shared row.
  - Unchanged: implementation of method invocation code.
  - Penalty: if classes C1 and C2 share the same row and C1 implements method m whereas C2 does not, then the code for m should begin with a check that control was reached via dispatching on an object of type C1.

Devirtualization

Devirtualization is a technique to reduce the overhead of virtual method invocation.

The aim of this technique is to statically determine which methods can be invoked by virtual method calls.

- If exactly one method is resolved for a method call, the method can be inlined or the virtual method call can be replaced by a static method call.

The analyses necessary for devirtualization also improve the accuracy of the call graph and the accuracy of subsequent interprocedural analyses.

Class Hierarchy Analysis

The simplest devirtualization technique is class hierarchy analysis (CHA), which determines the class hierarchy used in a program.

The information about all referenced classes is used to create a conservative approximation of the class hierarchy.

- The transitive closure of all classes referenced by the class containing the main method is computed.
- The declared types of the receiver of a virtual method call are used for determining all possible receivers.

Example: Class Hierarchy Analysis

```
class A extends Object {
    void m1() {...}
    void m2() {...}
    }
class B extends A {
    void m1() {...}
    }
class C extends A {
    void m1() {...}
    public static void main(...) {
        A a = new A();
        B b = new B();
        ...
        a.m1(); b.m1(); b.m2();
        }
    }

Rapid Type Analysis (1)

Rapid type analysis uses the fact that a method m of a class c can be invoked only if an object of type c is created during the execution of the program.

- It refines the class hierarchy (compared to CHA) by only including classes for which objects can be created at runtime.

Based on this idea

- pessimistic
- optimistic

algorithms are possible.

16.2

Rapid Type Analysis (2)

1. The pessimistic algorithm

...includes all classes in the class hierarchy for which instantiations occur in methods of the call graph from CHA.

2. The optimistic algorithm

- Initially assumes that no methods besides *main* are called and that no objects are instantiated.
- It traverses the call graph initially ignoring virtual calls (marking them in a mapping as potential calls only) following static calls only.
- When an instantiation of an object is found during analysis, all virtual methods of the corresponding objects that were left out previously are then traversed as well.
- The live part of the call graph and the set of instantiated classes grow interleaved as the algorithm proceeds.

Using Devirtualization Information

Inlining is an important usage of devirtualization information.

If a virtual method call can be devirtualized

- it might completely be replaced by inlining the call (supposed it is not recursive).

Escape Analysis

The goal of escape analysis is to determine which objects have lifetimes which do not stretch outside the lifetime of their immediately enclosing scopes.

- The storage for such objects can be safely allocated as part of the current stack frame – that is, their storage can be allocated on the run-time stack.
- At method return, deallocation of the memory space used by non-escaping objects is automatic. No garbage collection is required.
- The transformation also improves the data locality of the program and, depending on the computer's cache, can significantly reduce execution time. Objects not escaping a thread can be allocated in the processor where that thread is scheduled.

16.2

Using Escape Information

Objects whose lifetimes are confined to within a single scope cannot be shared between two threads.

- Synchronization actions for these objects can be eliminated.

Escape Analysis by Abstract Interpretation

A prototype implementation of escape analysis was included in the IBM High Performance Compiler for Java.

The approach of Choi et al. (OOPSLA'99) attempts to determine whether the object

- escapes from a method (i.e. from the scope where it is allocated).
- escapes from the thread that created it
  - the object can escape a method but does not escape from the thread.

    Note: The converse is not possible (if it does not escape the method then it cannot escape the thread).

16.2

Essence of Choi et al.'s Approach

- Introducing of a simple program abstraction called connection graph:

  Intuitively, a connection graph captures the connectivity relationship between heap allocated objects and object references.

- Demonstrating that escape analysis boils down to a reachability problem within connections graphs:

  If an object is reachable from an object that might escape, it might escape as well.

Experimental Results Reported by Choi et al.

...based on 10 benchmark programs:

- Percentage of objects that may be allocated on the stack:
  Up to $70+\%$, with a median of 19%.
- Percentage of all lock operations eliminated:
  From 11% to 92%, with a median of 51%.
- Overall execution time reduction:
  From 2% to 23%, with a median of 7%.

These results make escape analysis and the optimizations based theron whorthwhile.

Escape States

The analysis uses a simple lattice to represent different escape states:

$$\begin{array}{c} \textit{NoEscape}\ (\top) \\ | \\ \textit{ArgEscape} \\ | \\ \textit{GlobalEscape}\ (\bot) \end{array}$$

State	Escapes the method	Escapes the thread
NoEscape	no	no
ArgEscape	may (via args)	no
GlobalEscape	may	may

Using Escape Information

All objects which are marked

- NoEscape: are stack-allocatable in the method where they are created.
- NoEscape or ArgEscape: are local to the thread in which they are created; hence synchronization statements in accessing these objects can be eliminated.

Connection Graphs

We are interested only in

- following the object O from its point of allocation.
- knowing which variables reference O.
- and which other objects are referenced by O fields.

We "abstract out" the referencing information, using a graph structure where

- a circle node represents a variable.
- a square node represents objects in the heap.
- an edge from circle to square represents a reference.
- an edge from square to circle represents ownership of fields.

Example: Connection Graphs

```
A a = new A();    // line L1
a.b1 = new B();   // line L2
a.b2 = a.b1;      // line L3
```

An edge drawn as a dotted arrow is called a deferred edge and shows the effect of an assignment from one variable to another (example: created by the assignment in line 3) $\rightsquigarrow$ improves efficiency of the approach.

16.1.2
16.2

Intraprocedural Abstract Interpretation

Actions for assignments involve an update of the connection graph.

- An assignment to a variable p kills any value the variable previously had. The kill function is called $byPass(p)$:

16.2

Analyzing Statements (1)

p = new C(); // line L The operation *byPass*(p) is applied. An object node labeled L is added to the graph - and nodes for the fields of C that have nonintrinsic types are also created and connected by edges pointing from the object node.

p = q; The operation *byPass*(p) is applied. A new deferred edge from p to q is created.

p.f = q; The operation *byPass* is *not* applied for f (no strong update!). If p does not point to any node in the graph a new (phantom) node is created. Then, for each object node connected to p by an edge, an assignment to the field f of that object is performed.

Chap. 16
16.1
16.1.1
16.1.2
16.2

Analyzing Statements (2)

p = q.f; If q does not point at any object node then a phantom node is created and an edge from q to the new node is added. Then $byPass(p)$ is applied and deferred edges are added from p to all the f nodes that q is connected to by field edges.

For each statement one graph represents the state of the program at the statement.

At a point where two or more control paths converge, the connection graphs from each predecessor statements are merged.

Interprocedural Abstract Interpretation (1)

Analyzing methods:

- It is necessary to analyze each method in the reverse order implied by the call graph.
- If method A may call methods B and C, then B and C should be analyzed before A.
- Recursive edges in the call graph are ignored when determining the order.
- Java has virtual method calls – at a method call site where it is not known which method implementation is being invoked, the analysis must assume that all of the possible implementations are called, combining the effects from all the possibilities.
- The interprocedural analysis iterates over all the methods in the call graph until the results converge (fixed point).

16.1.1
16.1.2

Interprocedural Abstract Interpretation (2)

- A call to a method M is equivalent to copying the actual parameters (i.e. the arguments being passed in the method call) to the formal parameters, then executing the body of M, and finally copying any value returned by M as its result back to the caller.
- If M has already been analyzed intraprocedurally following the approach described above, the effect of M can be summarized with a connection graph. That summary information eliminates the need to re-analyze M for each call site in the program.

Analysis Results (1)

After the operation *byPass* has been used to eliminate all deferred edges, the connection graph can be partitioned into three subgraphs:

Global escape nodes: All nodes reachable from a node whose associated state is *GlobalEscape* are themselves considered to be global escape nodes (Subgraph 1)

- the nodes initially marked as *GlobalEscape* are the static fields of any classes and instances of any class that implements the `Runnable` interface.

Argument escape nodes: All nodes reachable from a node whose associated state is *ArgEscape*, but are not reachable from a *Global Escape* node. (Subgraph 2)

- the nodes initially marked as *ArgEscape* are the argument nodes $a_1, \ldots, a_n$.

16.2

Analysis Results (2)

No escape nodes: All other nodes have *NoEscape* status. (Subgraph 3).

The third subgraph represents the summary information for the method because it shows which objects can be reached via the arguments passed to the method.

All objects created within a method *M* and that have the *NoEscape* status after the three subgraphs have been determined can be safely allocated on the stack.

Overview

Collection of Examples

- Definition of executable slice (liveness analysis)
- Example with scalar variables
- Example with pointers to stack-allocated variables
- Example with strong and weak update in alias analysis
- Example with non-cyclic dynamic data structures
- Example with cyclic data structures
- Comparison of slice size

A Conclusion

...a question for the sense of life, or for what we did achieve resp.

- What did we consider?

  The least!

Or vice versa...

- What did we not consider?

  The most!

Outlook

Emerging applications of (static) program analysis beyond optimization:

- Security Analysis
- Program Understanding
- Refactoring
- ...

...topics for master and PhD theses to come!

Sets and Relations (1)

Definition (A.1.1)

Let M be a set and R a relation on M, i.e. $R \subseteq M \times M$.

Then R is called

- reflexive iff $\forall\, m \in M.\ m\, R\, m$
- transitive iff $\forall\, m, n, p \in M.\ m\, R\, n \ \wedge\ n\, R\, p \ \Rightarrow\ m\, R\, p$
- anti-symmetric iff $\forall\, m, n \in M.\ m\, R\, n \ \wedge\ n\, R\, m \ \Rightarrow\ m = n$

Sets and Relations (2)

Related notions (though less important for us here):

Definition (A.1.2)

Let M be a set and $R \subseteq M \times M$ a relation on M. Then R is called

- symmetric iff $\forall\, m, n \in M.\ m\, R\, n \iff n\, R\, m$
- total iff $\forall\, m, n \in M.\ m\, R\, n \ \vee\ n\, R\, m$

Partially Ordered Sets

Definition (A.2.1, Quasi-Order, Partial Order)

A relation R on M is called a

- quasi-order iff R is reflexive and transitive
- partial order iff R is reflexive, transitive, and anti-symmetric

For the sake of completeness we recall:

Definition (A.2.2, Equivalence Relation)

A relation R on M is called an

- equivalence relation iff R is reflexive, transitive, and symmetric

Contents

Bounds, least and greatest Elements

Definition (A.2.3, Bounds, least/greatest Elements)

Let $(Q, \sqsubseteq)$ be a quasi-order, let $q \in Q$ and $Q' \subseteq Q$.

Then q is called

- upper (lower) bound of Q', in signs: $Q' \sqsubseteq q$ ($q \sqsubseteq Q'$), if for all $q' \in Q'$ holds: $q' \sqsubseteq q$ ($q \sqsubseteq q'$)
- least upper (greatest lower) bound of Q', if q is an upper (lower) bound of Q' and for every other upper (lower) bound $\hat{q}$ of Q' holds: $q \sqsubseteq \hat{q}$ ($\hat{q} \sqsubseteq q$)
- greatest (least) element of Q, if holds: $Q \sqsubseteq q$ ($q \sqsubseteq Q$)

Existence and Uniqueness of Bounds

We have:

- Given a partial order, least upper and greatest lower bounds are uniquely determined, if they exist.
- Given existence (and thus uniqueness), the least upper (greatest lower) bound of a set $P' \subseteq P$ of the basic set of a partial order $(P, \sqsubseteq)$ is denoted by $\bigsqcup P'$ ($\bigsqcap P'$). These elements are also called supremum and infimum of P'.
- Analogously this holds for least and greatest elements. Given existence, these elements are usually denoted by $\bot$ and $\top$.

Lattices and Complete Lattices

Definition (A.3.1, (Complete) Lattice)

Let $(P, \sqsubseteq)$ be a partial order.

Then $(P, \sqsubseteq)$ is called a

- lattice, if each finite subset P' of P contains a least upper and a greatest lower bound in P.
- complete lattice, if each subset P' of P contains a least upper and a greatest lower bound in P.

Hence:
...(complete) lattices are special partial orders.

Properties of Complete Lattices

Lemma (A.3.2)

Let $(P, \sqsubseteq)$ *be a complete lattice. Then we have:*

1. $\bot = \bigsqcup \emptyset = \bigsqcap P$ *is the least element of* P.
2. $\top = \bigsqcap \emptyset = \bigsqcup P$ *is the greatest element of* P.

Lemma (A.3.3)

Let $(P, \sqsubseteq)$ *be a partial order. Then the following claims are equivalent:*

1. $(P, \sqsubseteq)$ *is a complete lattice.*
2. *Every subset of* P *has a least upper bound.*
3. *Every subset of* P *has a greatest lower upper bound.*

Complete Partial Orders

...a slightly weaker notion than a lattice that, however, is often sufficient in computer science and thus often a more adequate notion:

Definition (A.4.1, Complete Partial Order)

Let $(P, \sqsubseteq)$ be a partial order.

Then $(P, \sqsubseteq)$ is called

- complete, or shorter a CPO (complete partial order), if each ascending chain $C \subseteq P$ has a least upper bound in P.

Contents

Chains

Definition (A.4.2, Chain)

Let $(P, \sqsubseteq)$ be a partial order.

A subset $C \subseteq P$ is called

- chain of P, if the elements of C are totally ordered. For $C = \{c_0 \sqsubseteq c_1 \sqsubseteq c_2 \sqsubseteq \ldots\}$ ($\{c_0 \sqsupseteq c_1 \sqsupseteq c_2 \sqsupseteq \ldots\}$) we also speak more precisely of an ascending (descending) chain of P.

A chain C is called

- finite, if C is finite; infinite otherwise.

Finite Chains, finite Elements

Definition (A.4.3, Chain-finite)

A partial order $(P, \sqsubseteq)$ is called

- chain-finite (German: kettenendlich) iff P does not contain infinite chains

Definition (A.4.4, Finite Elements)

An element $p \in P$ is called

- finite iff the set $Q =_{df} \{q \in P \mid q \sqsubseteq p\}$ is free of infinite chains
- finite relative to $r \in P$ iff the set $Q =_{df} \{q \in P \mid r \sqsubseteq q \sqsubseteq p\}$ does not contain infinite chains

(Standard) CPO Constructions (2)

Product construction.

Let $(P_1, \sqsubseteq_1), (P_2, \sqsubseteq_2), \ldots, (P_n, \sqsubseteq_n)$ be CPOs. Then

- the non-strict (direct) product $(\bigtimes P_i, \sqsubseteq)$ with
  - $(\bigtimes P_i, \sqsubseteq) = (P_1 \times P_2 \times \ldots \times P_n, \sqsubseteq)$ with $\forall\, (p_1, p_2, \ldots, p_n),$ $(q_1, q_2, \ldots, q_n) \in \bigtimes P_i.\ (p_1, p_2, \ldots, p_n) \sqsubseteq (q_1, q_2, \ldots, q_n) \Leftrightarrow \forall\, i \in \{1, \ldots, n\}.\ p_i \sqsubseteq_i q_i$
- and the strict (direct) product (smash product) with
  - $(\bigotimes P_i, \sqsubseteq) = (P_1 \otimes P_2 \otimes \ldots \otimes P_n, \sqsubseteq)$, where $\sqsubseteq$ is defined as above under the additional constraint:

$$(p_1, p_2, \ldots, p_n) = \bot \Leftrightarrow \exists\, i \in \{1, \ldots, n\}.\ p_i = \bot_i$$

are CPOs, too.

Monotonic, Continuous Functions on CPOs

Definition (A.4.5, Monotonic, Continuous Function)

Let $(C, \sqsubseteq_C)$ and $(D, \sqsubseteq_D)$ be two CPOs and let $f : C \to D$ be a function from C to D.

Then f is called

- monotonic iff $\forall\, c, c' \in C.\ c \sqsubseteq_C c' \Rightarrow f(c) \sqsubseteq_D f(c')$
  (Preservation of the ordering of elements)
- continuous iff $\forall\, C' \subseteq C.\ f(\bigsqcup_C C') =_D \bigsqcup_D f(C')$
  (Preservation of least upper bounds)

Least and Greatest Fixed Points

Definition (A.5.1, (Least/Greatest) Fixed Point)

Let $(C, \sqsubseteq)$ be a CPO, $f : C \to C$ be a function on C and let c be an element of C, i.e., $c \in C$.

Then c is called

- fixed point of f iff $f(c) = c$

A fixed point c of f is called

- least fixed point of f iff $\forall\, d \in C.\ f(d) = d \Rightarrow c \sqsubseteq d$
- greatest fixed point of f iff $\forall\, d \in C.\ f(d) = d \Rightarrow d \sqsubseteq c$

Notation:

- The least resp. greatest fixed point of a function f is usually denoted by μf resp. νf.

Proof of Fixed Point Theorem A.5.3 (2)

1. Existence
   - It holds $f^0 \perp = \perp$ and $\perp \sqsubseteq c$ for all $c \in C$.
   - By means of (natural) induction we can show: $f^n \perp \sqsubseteq f^n c$ for all $c \in C$.
   - Thus we have $f^n \perp \sqsubseteq f^m \perp$ for all n, m with $n \leq m$. Hence, $\{f^n \perp \mid n \geq 0\}$ is a (non-finite) chain of C.
   - The existence of $\bigsqcup_{i \in \mathbb{N}_0} f^i(\perp)$ is thus an immediate consequence of the CPO properties of $(C, \sqsubseteq)$.

Proof of Fixed Point Theorem A.5.3 (4)

3. Least fixed point

- Let c be an arbitrarily chosen fixed point of f. Then we have $\bot \sqsubseteq c$, and hence also $f^n \bot \sqsubseteq f^n c$ for all $n \geq 0$.
- Thus, we have $f^n \bot \sqsubseteq c$ because of our choice of c as fixed point of f.
- Thus, we also have that c is an upper bound of $\{f^i(\bot) \mid i \in \mathbb{N}_0\}$.
- Since $\bigsqcup_{i \in \mathbb{N}_0} f^i(\bot)$ is the least upper bound of this chain by definition, we obtain as desired $\bigsqcup_{i \in \mathbb{N}_0} f^i(\bot) \sqsubseteq c$.

Basic Block vs. Single Instruction Graphs

In this chapter we investigate the adequacy of different program representations.

To this end we will consider and compare programs in form of node and edge-labelled flow graphs with basic blocks and single instructions and investigate their

- advantages and disadvantages for program analysis

...thereby addressing the question:

- Basic Block vs. Single Instruction Graphs: Just a Matter of Taste?

On the fly we will learn:

- Some further examples of real world data flow analysis problems and data flow analyses.

Basic Blocks: Supposed Advantages

Advantages of basic blocks in applications that are commonly attributed to them ("folk knowledge"):

Better scalability because

- less nodes are involved in the (potentially) compu- tationally expensive fixed point iteration and thus
- larger programs fit into the main memory.

Basic Blocks: Definite Disadvantages

Definite disadvantages of basic blocks in applications:

- Higher conceptual complexity: Basic blocks introduce an undesired hierarchy into flow graghs that makes both theoretical reasoning and practical implemenentations more difficult.
- Necessity of pre- and post-processes: These are usually required in order to cope with the additional problems introduced by the hierarchical structure of basic block flow graph (e.g. in dead code elimination, constant propagation,...); or that require "tricky" formulations to avoid them (e.g. in partial redundancy elimination).
- Limited generality: Some practically relevant program analyses and optimizations are difficult or not at all expressible on the level of basic block flow graphs (e.g. faint variable elimination).

Notations

In the following we denote

- basic block nodes by boldface letters (**m**, **n**,...)
- single instruction nodes by normalface letters (m, n,...)

Furthermore we denote by

- $[\![\ ]\!]_\beta$ and
- $[\![\ ]\!]_\iota$

(local) abstract data flow analysis functionals on the level of basic blocks and single instructions, respectively.

Outlook

Next we consider two further examples in order to illustrate the impact of the chosen flow graph representation variant on the conceptual and practical complexity of data flow analysis:

- Constant propagation and folding
- Faint variable elimination

To this end we consider formulations of these problems for:

- node-labelled basic-block flow grapns
- edge-labelled single instruction flow graphs

Backward Substitution and State Transformation for Assignments

Let $\iota \equiv (x := t)$ be a statement. Then we define:

- Backward substitution

  $\delta_\iota : \mathbf{T} \to \mathbf{T}$ by $\delta_\iota(s) =_{df} s[t/x]$ for all $s \in \mathbf{T}$, where $s[t/x]$ denotes the simultaneous replacement of all occurrences of x by t in s.

- State transformation

$$\theta_\iota(\sigma)(y) =_{df} \begin{cases} \mathcal{E}(t)(\sigma) & \text{if } y = x \\ \sigma(y) & \text{otherwise} \end{cases}$$

The Relationship of δ and θ

Let $\mathcal{I}$ denote the set of all statements.

Lemma (B.3.1, Substitution Lemma)

$$\forall\, t \in \mathbf{T}\ \forall\, \sigma \in \Sigma\ \forall\, \iota \in \mathcal{I}.\ \mathcal{E}(\delta_\iota(t))(\sigma) = \mathcal{E}(t)(\theta_\iota(\sigma))$$

Proof by induction on the structure of t.

Backward Substitution and State Transformation on Paths

Extending δ and θ to paths (and hence to basic blocks, too):

- $\Delta_p : \mathbf{T} \to \mathbf{T}$ defined by $\Delta_p =_{df} \delta_{n_q}$ for $q = 1$ and by $\Delta_{(n_1,\ldots,n_{q-1})} \circ \delta_{n_q}$ for $q > 1$
- $\Theta_p : \Sigma \to \Sigma$ defined by $\Theta_p =_{df} \theta_{n_1}$ for $q = 1$ and by $\Theta_{(n_2,\ldots,n_q)} \circ \theta_{n_1}$ for $q > 1$.

Motivation

Statement

- $l := l + 1$ is live.
- $t := u + v$ is dead.
- $s := s + 1$ as well as $s1 := s2;\ s2 := s1$ are live but faint (schwach, kraftlos, ohnmächtig, schattenhaft).

Preliminaries

...for edge-labelled single instruction flow graphs.

Local Predicates (associated with single instruction edges):

- $\text{USED}_\varepsilon(v)$: Statement ι of edge ε uses v.
- $\text{MOD}_\varepsilon(v)$: Statement ι of edge ε modifies v.
- $\text{REL-USED}_\varepsilon(v)$: v is a variable that occurs in the statement ι of the edge ε and "is forced to live" by it (e.g. for ι being an output operation).
- $\text{ASS-USED}_\varepsilon(v)$: v is a variable that occurs in the right-hand side expression of the assignment ι of the edge ε.

Summary

The faint variables problem is an example of a DFA problem, for which a formulation is

- obvious on (node- and edge-labelled) single instruction flow graphs,
- not at all obvious, if not impossible at all on (node- and edge-labelled) basic-block flow graphs.

Conclusion

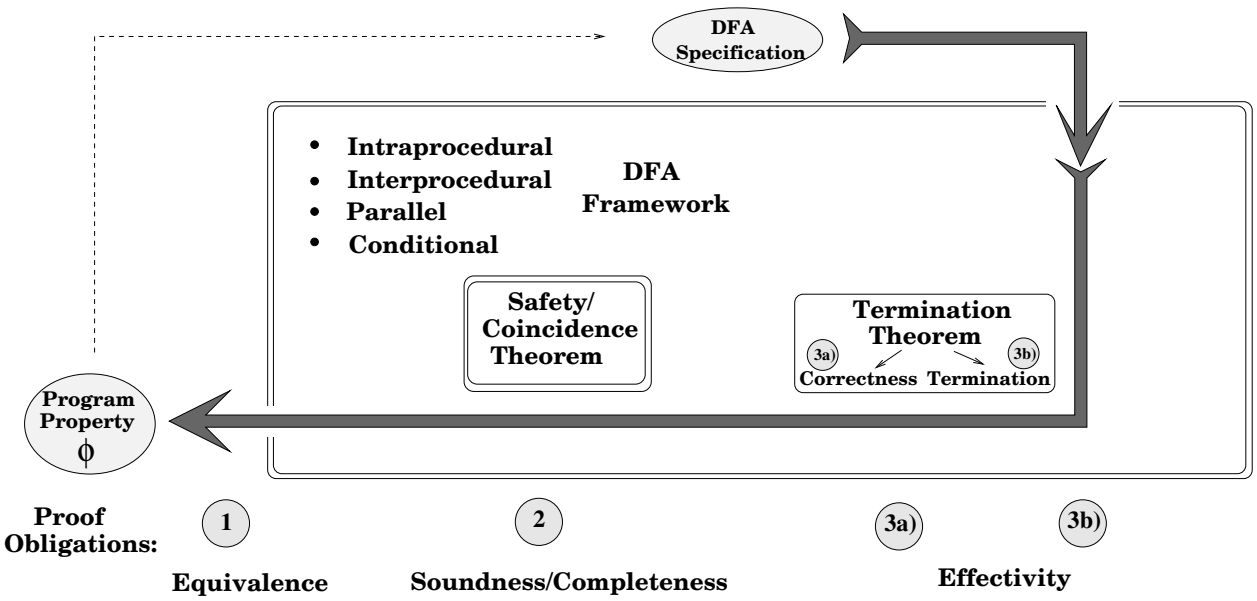
In principle, all 4 representation variants of flow graphs are equally powerful.

Hence, conceptually the general framework resp. tool kit view



and knowing that the variants differ in their adequacy and in the specification, implementation and proof obligations they require depending on the task at hand suffices.
